timidating its adversary with potentially life-threatening defenses (horns), broad-body/appendage circumference and pseudo-defenses (pointed lateral-fringe scales). Unlike the "dorsal shield" response of *P. cornutum* to *Masticophis* spp. (Sherbrooke 2008), the body-flipping response of *P. solare*, once assumed, does not allow continuous adjustments of defensive positioning by the inverted lizard. Nevertheless, we noted increased rigidity of limbs and further raising of horns, possible antipredator adjustments, during our simulations of snake biting by pinching (dorso-ventrally) the edge of inverted lizards' bodies (unpubl. data, Sherbrooke and May). As a defense against ingestion by gape-limited snakes, body-flipping and immobility in *P. solare* resembles defenses in some anguid and cordylid lizards. When threatened by colubrid snakes, they effect body conformation changes by grasping their tail in their jaws to create a broad circular body form that is difficult or impossible for snakes to ingest (Arnold 1993; Fitch 1935; Mouton et al. 1999).

The apparent visual monitoring for the continued presence of *M. flagellum* by the lizards (by opening their eyelids), and the short duration of the time lizards spent resting in an inverted position once the snake was removed (usually < 1 min) suggests that the lizards, once flipped, remained open to subsequent running escapes from the snake encounter site. The duration of immobility may be influenced by access to escape routes and absence of predator threat (Burghardt and Greene 1988; Hennig et al 1976; O'Brien and Dunlap 1975). Repeated body-flips by *P. solare* during multiple-interrupted encounters of the trials (Table 1) illustrate the significance of the presence or absence of the predator threat to the lizard assuming the flipped and immobile posture.

In contrast to *M. flagellum*, *C. atrox* do not rapidly pursue prey, but strike nearby prey with a venomous injection from their fangs, from which a horned lizard has no chance of survival (Sherbrooke 2008; Sherbrooke and May 2008). Prevention of envenomation may be best accomplished by avoidance, which *P. solare* accomplishes by running to quickly remove itself from the vicinity of *C. atrox*. *Crotalus atrox* is unlikely to pursue an unenvenomated lizard. In contrast to this appropriate escape behavior, assumption of a body-flip and immobility stance by *P. solare* to a *C. atrox* threat would only facilitate prey capture and subjugation (envenomation). Thus, in response to two predator threats, *P. solare* appears to identify the category of snake predator involved and responds to each with a distinct defensive behavior that may enhance its potential for survival in each of two distinctly-different predation scenarios, non-venomous and venomous snakes.

We consider body-flipping behavior by *P. solare* to be an adaptive survival response involving honest presentation and amplification (Taylor et al. 2000) of prey resistance abilities to subjugation and consumption by a gape-limited predator. This is in contrast to the death-feigning hypothesis (untested) that prey death-feigning (tonic immobility, etc.) might have intrinsic survival value, without a clear explanation of how it functions in enhancing prey survival (Honma et al. 2006; Ruxton 2006; Ruxton et al. 2004). Although we see no support from our study for the death-feigning hypothesis, we note that the two hypotheses are not mutually exclusive: both display of features of morphological resistance and immobility per se may contribute to prey survival.

Acknowledgments.—A VHS copy of a Chicago Academy of Science film of Gloyd's Arizona expedition was supplied by R. Vasile. Access to King Anvil Ranch, Altar Valley, Pima Co., Arizona, was provided by J. and P. King. Comments on the manuscript by G. D. Ruxton helped us to clarify and extend issues considered in the discussion. Arizona Game and Fish Department provided scientific collecting Permit A01124495; American Museum of Natural History IACUC protocol was followed.

Caecilians are limbless, subterranean or aquatic amphibians found throughout much of the tropics (Duellman and Trueb 1994; Himstedt 1996). Although amphibians are declining dramatically (Stuart et al. 2004), the conservation status of caecilians is largely unknown due to lack of information on their ecology and natural history (Gower and Wilkinson 2005). A handful of studies have documented caecilian life histories (e.g., Funk et al. 2004; Gans 1961; Kupfer et al. 2005; Malonza and Measey 2005; Parker 1936, 1958; Sanderson 1937; Sarasin and Sarasin 1887–1890; Taylor 1968; Wake 1980). Nevertheless, 114 out of 172 species (66%) of caecilians remain too poorly known for an accurate status assessment, and thus are listed as "Data Deficient" by the IUCN (2006). Perhaps because of their elusive nature, there is an increasing interest in the biology of caecilians (Kupfer et al. 2006; Measey and Herrel 2006).

Predator-prey interactions are widely recognized to have important effects on population dynamics (e.g., Krebs et al. 1995; Lotka 1925; Volterra 1926), but in the case of caecilians, little is even known about which taxa act as predators. Snakes are considered the main predators of caecilians (Duellman and Trueb 1994; Kupfer et al. 2003), although some other predators such as turtles (Zamprogno and Zamprogno 1998), spiders (Boistel and Pauwels 2002), and ants (Measey 2004) have been documented preying on caecilians. Identifying predators of amphibians is important in the context of amphibian declines, because predation may tip already declining populations over the edge toward extinction (Corn 1993; Parker et al. 2000). Here we show that a tropical hawk acts as an important predator of the caecilian *Caecilia orientalis* and that this unexpected ecological interaction depends strongly on weather.

Methods.—We filmed a Barred Hawk (*Leucopternis princeps*) nest using a hidden camera from 15 February–8 May 2004 and 7–28 January 2005 for a total of 599 h in the private reserve of Cabañas San Isidro, next to Yanayacu Biological Station (00°35'S, 77°53'W; 1950 m elev.). During most days of filming, the nest was filmed continuously during daylight hours (from morning to evening) when the hawks were active. The Barred Hawk is a rare, large hawk (total length = 52–61 cm) found from northern Peru to Costa Rica (700–2200 m; Ridgely and Greenfield 2001). The 1700 ha reserve comprises a mosaic of primary and secondary growth in humid, montane, evergreen forest about 3 km W of the town of Cosanga in the Napo Province of northeastern Ecuador (for a more complete site description, see Greeney et al. 2006).

Each year, the same Barred Hawk pair raised a single chick in the same nest. The nest was located on a rocky ledge 5 m from a rushing waterfall. The blind was installed 3.5 m above and 10 m from the nest, on the opposite side of a stream. All videos were transcribed at a later date. In addition to recording prey brought to the nest, we recorded whether it rained during each hour-long time interval. Since video quality was excellent, most taxa were clearly identifiable, but seven unknown taxa were excluded from the analysis. Because caecilians surface primarily during heavy rains and snakes are active at Yanayacu when it is clear and sunny, we hypothesized that Barred Hawks would bring more caecilians to the nest, but fewer snakes, when it was raining. We tested this in 2004 using a Fisher's exact test. This was the second Barred Hawk nest ever documented (Muela and Valdez 2003) and the first closely monitored to document feeding behavior. Details of the breeding ecology of these Barred Hawks are being prepared separately for an ornithological journal (R. A. Gelis and H. F. Greeney, unpubl. ms.).

Results.—To our surprise, a caecilian species (*Caecilia orientalis*) was the main prey item brought to the nest by two Barred Hawk parents to feed a single chick brooded each year (Fig. 1; videos available upon request). *Caecilia orientalis* is a large caecilian (total length = 31–62.5 cm) found in the Andes of Ecuador and Colombia and is the only caecilian known from this site (Funk et al. 2004; IUCN 2006). Prey items delivered to nestlings included 50 caecilians (48.1% of diet), 36 snakes (34.6%; *Atractus occipitoalbus* and two unidentified colubrid species), five giant

A color version of this photo is available upon request. (B) Proportion of Barred Hawk diet in 2004 and 2005 composed of different taxa. (C) Barred Hawks bring significantly more caecilians than snakes to the nest when it is raining ($P < 0.00001$, N = 58).

earthworms (4.8%), three young birds (2.9%), three small mammals (2.9%), and seven unknown animals (6.7%) (Fig. 1B). *Caecilia orientalis* vouchers from this site are available in the Museo de Zoología at the Pontificia Universidad Católica del Ecuador (QCAZ 21417–21419).

As predicted, we found that Barred Hawks brought significantly more caecilians than snakes to the nest during hour-long time intervals when it was raining (Fisher's exact test, $P < 0.00001$, N = 58; Fig. 1C).

Discussion.—It is surprising that an aerial predator, the Barred Hawk, was able to find subterranean prey such as caecilians. A previous report states that birds may occasionally prey on caecilians (Wake 1983), but this report did not provide specific bird species names or details of this predator-prey interaction. During several years of research at Yanayacu, caecilians were rarely encountered on the surface in the day even when it was raining (Funk et al. 2004). Thus it is unknown how Barred Hawks are able to consistently find these elusive amphibians. These results suggest that *Caecilia orientalis* may actually be fairly common, as has been found for some other caecilian species (Measey 2004), yet *C. orientalis* is reported as "uncommon in Ecuador" by the Global Amphibian Assessment (IUCN 2006). Because of the rarity and huge ranges of Barred Hawks, we were only able to find and intensively monitor one pair over two years. It will likely take several years of intensive searching to find additional Barred Hawk nests. Nonetheless, the dominance of caecilians in this pair's diet and consistent use of these amphibians over two years suggests that caecilian predation by Barred Hawks will likely be widespread at sites with abundant caecilian populations.

Rainfall has increased at some sites in Ecuador over the last 40 years (Haylock et al. 2006), although rainfall trends at Yanayacu are unknown. If predation on caecilians is typical for Barred Hawks, changes in rainfall could alter this predator-prey interaction and potentially impact populations of both species. Climate change has already been implicated in amphibian declines in Ecuador and elsewhere in the Neotropics (Blaustein and Dobson 2006; Pounds et al. 2006). Predicting the ecological impacts of climate change, however, will require a better understanding of trophic interactions and the influence of weather on these interactions as documented here.

Determining the effect of predators on caecilian populations will also require a much better understanding of caecilian population dynamics. Studying the population ecology of these fossorial amphibians has proven difficult in the past due to low detectability, a paucity of methods for individually marking caecilians, and the rareness of some caecilians species. However, at Yanayacu Biological Station and some other sites (Bustamante 2005; Measey 2004; Péfaur et al. 1987), caecilians can be abundant and thus potentially amenable to study. New methods have also recently been developed for marking caecilians for capture-recapture estimation of vital rates and demographic parameters (Gower et al. 2006; Measey et al. 2001, 2003). Use of these methods in combination with population modeling (Biek et al. 2002) and molecular genetic markers (Beebee 2005; Funk et al. 2005) should help illuminate the demography, ecology, and conservation status of these fascinating animals.

Acknowledgments.—We thank Carmen Bustamante for permission to conduct research on the San Isidro Reserve. We also thank J. Beatty, L. Coloma, D. Gower, J. Matthews, J. Measey, and A. Sheldon for comments on the manuscript. Funding was provided by Matt Kaplan, John V. and Ruth Ann Moore, a Pamela and Alexander F. Skutch Award, and a Declining Amphibian Populations Task Force Seed Grant. This study was conducted in compliance with Ecuadorian laws. This is publication number 59 of the Yanayacu Natural History Research Group.

Polypedates leucomystax (Rhacophoridae) is among the most common of the nearly 800 species of anurans in southeast Asia (Iskandar and Colijn 2000), and among the most widespread, ranging from southern China south to Indonesia, and from India to the Philippines. Compared to most anurans of tropical southeast Asia, there are several reports on its habitat (Garcia-Rutledge and Narins 2001; Inger and Steubing 1997; Malkmus et al. 2002; Narins et al. 1998), calls (e.g., Christensen-Dalsgaard et al. 2002; Sheridan 2008) and reproductive habits (Feng and Narins 1991; Malkmus et al. 2002; Yorke 1983). Despite this, relatively little is known of its population size, sex ratio, and variation in reproduction. In this paper, I present a detailed study of reproduction (clutch size and variation therein), time to metamorphosis, adult body size, and male site fidelity at a seasonal site (Sakaerat, Thailand) to allow for an evaluation of variation in these traits across the broad range of *P. leucomystax*. My observations permit the exploration of the adaptations seen in other tropical anurans that range from aseasonal to seasonal environments.

Polypedates leucomystax is a medium-sized tree frog (male SVL 37–64 mm, female SVL 57–89 mm) common in disturbed areas. It breeds in standing water such as natural ponds, cattle tanks, cisterns, and flower pots. Males form calling groups around standing water and females create foam nests above water in emergent vegetation or other suitable substrate (e.g., cistern wall). In some cases, multiple males will clasp a single female during a given breeding event (Feng and Narins 1991; pers. obs.). In Singapore, eggs have been found in January, February, April, August, and September, and females had enlarged oviducts in all months in which they were captured (all months except May, July, and November, Berry 1964). Zeller (1960) reported that they can breed throughout the year but are inhibited by dry conditions in western Java. Yorke (1983) noted that near Kuala Lumpur, Malaysia, the females deposit 100–400 eggs in foam masses measuring about 10 cm in length on vegetation above ephemeral ponds. In Sabah, Malaysia, Malkmus et al. (2002) found larger clutch sizes, 150–900 eggs. Time to metamorphosis was reported as 4 weeks at Sakaerat, northeast Thailand (Heyer 1973), and 7 weeks in Kuala Lumpur (Yorke 1983).

Polypedates leucomystax is not a well-defined species and is probably a complex of cryptic sympatric and allopatric taxa. Narins et al. (1998) reported significant differences in calling habits of two genetically distinct sympatric morphotypes of *P. leucomystax* near Kuala Lumpur, but did not propose new nomenclature. Within the Sakaerat, Thailand, population, Sheridan (2008) found no significant differences in calls, and analysis of 500 bp of the 16S gene indicated variation of less than 1%. Thus, all individuals encountered at Sakaerat are likely conspecific, but further studies of call, genetic, and morphological variation are necessary to determine how this population of *P. leucomystax* is related to others.

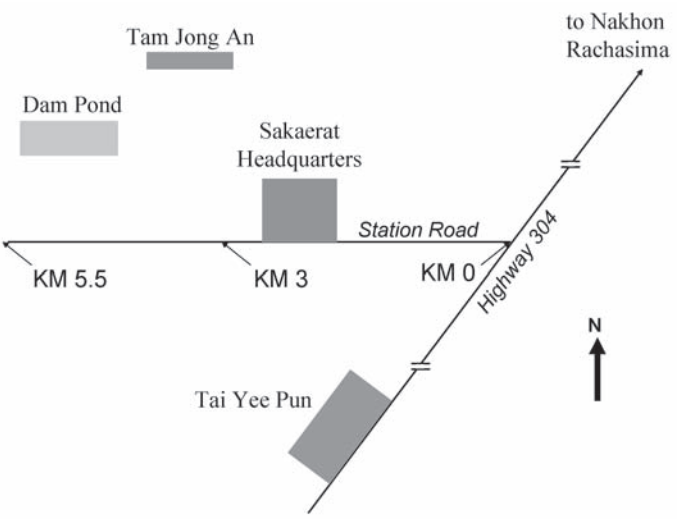

Fig. 1. Schematic diagram of study areas of *Polypedates leucomystax* breeding at Sakaerat, Thailand. Image not to scale. Tai Yee Pun is 7 km south of Sakaerat headquarters.

Methods.—I conducted this study from April to September 2005 (except for call recordings as noted below) at Sakaerat Environmental Research Station (14.5°N, 101.92°E), Thailand. This forested region is 60 km S of Nakhon Ratchasima and 250 km NE of Bangkok on the northeastern slope of the central highlands at the edge of the Korat Plateau. I monitored five areas during the rainy season between 25 April and 4 September 2005. Annual mean rainfall is 1240 mm and there is a marked dry season from November through March. The 78 km^2 area is 70% dry dipterocarp and dry evergreen forest, with the remaining area comprised of grasslands, bamboo, and plantation forests (Heyer 1973; Lynam et al. 2006). Elevation ranges between 280 and 762 m above sea level at the site, but all study areas were below 600 m. I selected areas in different habitat types, including dry dipterocarp forest, dry evergreen forest, two types of pond systems, and a cleared area (Fig. 1). For logisitical reasons, two areas (Tam Jong An and Tai Yee Pun) were added to the study at 3 and 5 weeks, respectively. For a full description of each study area, see Appendix 1.

Each area was surveyed 1–3 times per week between 1900 h and 000 h. Frogs were detected by eye-shine and vocalizations. All adult *P. leucomystax* encountered were measured for snout-vent length (SVL) using a ruler, individually marked according to Hero (1989), and released at point of capture. Sex was determined by size, calling behavior, or presence of male nuptial pads. In this species, females are larger than males, so any individual between 35 and 60 mm, heard calling, or with nuptial pads was assumed to be a male. All individuals above 70 mm were assumed to be female (no individuals measuring 65–70 mm SVL were found). Voucher specimens were deposited in the Natural History Museum of Chulalongkorn University, Bangkok.

Areas were searched in the morning at least every other day for foam-covered egg masses. Within 36 hours of discovery, eggs were staged (Gosner 1960) and counted. If eggs were at or below stage 13, diameter of ten eggs was measured under a dissecting scope to

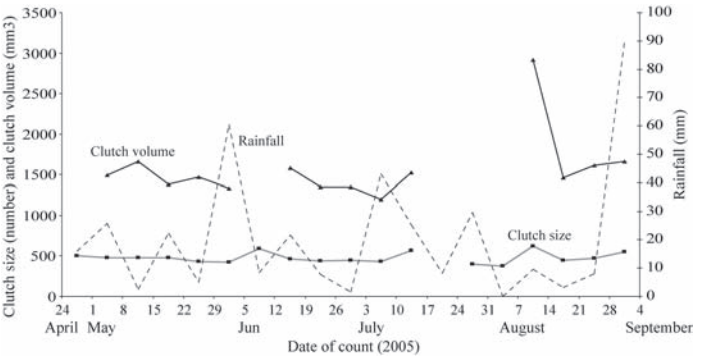

Fig. 3. Mean clutch size (number of eggs, solid line and squares) and mean clutch volume (mm^3, solid line and triangles) of *Polypedates leucomystax*, and rainfall (mm, dashed line and diamonds) at Sakaerat Environmental Research Station, Thailand.

the nearest 0.01 mm with digital calipers, averaged to give a mean egg size per clutch, and used to calculate clutch volume ((2/3*3.14*(radius of egg)^3)*clutch size). Eggs of this species lack jelly capsules, making it easy to obtain ovum size.

Time to metamorphosis for *P. leucomystax* was determined in 7 L round plastic basins, 35 cm in diameter. A single clutch was divided among eleven basins with thirteen tadpoles each when tadpoles were at developmental stage 25 (Gosner 1960). Tadpoles were given algae water once a week and fed commercial aquarium fish food (flakes and pellets). Basins were kept in a shade house with plastic roofing to prevent exposure to rainfall and direct sunlight. Nighttime water temperatures in cement basins in the forests of Sakaerat were 26.0 ± 0.2°C during the study period and that of the experimental basins was assumed to be similar. Mean daytime air temperature fell from 35.4°C in April to 30.0°C in September.

Calls were recorded between 5 July and 30 September 2006 using a Sony WM D6C Professional Walkman Cassette Recorder and an Audio-technica condenser. Calls were digitized using Windows Sound Recorder at 44.1 kHz. Audiospectrograms and oscillograms were produced and quantified by Raven Software 1.2.

Results.—I marked 225 *P. leucomystax* (174 males, 31 females, and 20 juveniles) over 150 search nights. Males were commonly

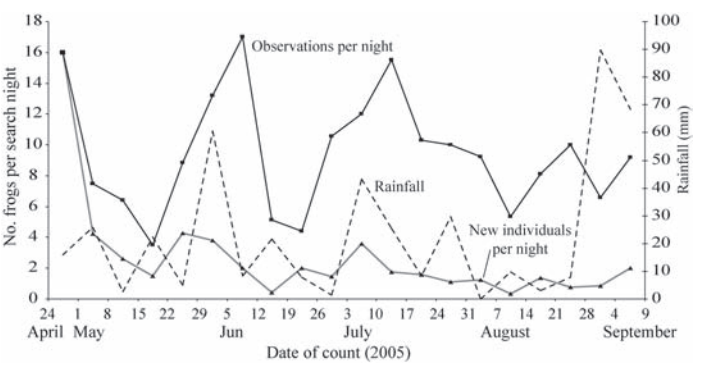

Fig. 2. Number of individual *Polypedates leucomystax* observed per search night (solid line and squares) and number of new individuals per search night (solid line and triangles) at Sakaerat, Thailand. Rainfall (mm, dashed line and diamonds) is also shown.

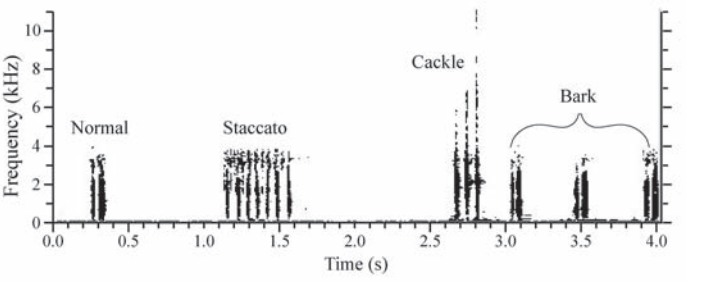

Fig. 4. Spectrogram of calls made by *Polypedates leucomystax* at Sakaerat, Thailand. Call elements are from a single individual but did not occur consecutively; call elements were cut and pasted from a 5 minute recording.

encountered and were heard calling even when no females were observed. Across weeks, the mean ± SE number of observations per night was 9.35 ± 0.87 (range = 3.5–17, N = 19). Mean ± SE male SVL was 55.05 ± 0.24 mm (range = 43–65 mm) and that for females was 79.0 ± 0.69 mm (range = 71–89 mm). Overall recapture rate during the study period was 75% for males and 29% for females (Table 1). Most of the locations where males were encountered were spaced such that determining site fidelity to an accuracy of 20 m was possible for 98 of the 130 recaptured males. Of these 98, 72 (73 %) were only ever encountered within 20 m of their original capture point, and 26 (27%) were encountered at least one time more than 20 m from their original capture point. Rainfall did not influence total observations or new individuals per search night (regression $R^2 < 0.01$ for both; see Fig. 2). After the first week of surveys, the number of new individuals per search night each week was 1.94 ± 0.28 (N = 19) which represented 23.3 ± 3.7% of the total observations per search night each week.

I counted eggs of 76 *P. leucomystax* clutches. Number of clutches found per week ranged between 1–15 (mean ± SE = 3.07 ± 0.76) and differed between weeks ($\chi^2 = 52.9$, $P < 0.01$). However, this variation between weeks is due to a single week in which 15 clutches were found, and was the week in which an additional area (Tai Yee Pun) was added to my searches. Number of clutches found in a given week did not change predictably over the study period and was not dependent on rainfall (regression $R^2 = 0.01$). An additional 10 clutches were not included in the analyses because ova could not be counted accurately due to their late stage of development or the presence of insect larvae which appeared to have eaten a large number of eggs. Mean ± SE clutch size for the entire study period was 454.45 ± 12.41 (range = 230–804; N = 76), mean ± SE egg diameter was 1.81 ± 0.02 mm (N = 37), and mean ± SE clutch volume was 1494.79 ± 75.11 mm^3 (N = 37). Not all clutches were used to calculate clutch volume because some clutches were found after eggs had passed developmental stage 13 (Gosner 1960). Dissections of preserved females and from females collected immediately after oviposition indicated that females contain eggs at different stages of development at any given time, but that all eggs of a given size class were oviposited at once (Sheridan 2008).

There was no difference in clutch size (ANOVA F-value = 0.76, $P > 0.70$) or clutch volume (ANOVA F-value = 0.60, $P > 0.85$) between weeks (Fig. 3). Clutch size and clutch volume were unrelated to rainfall in a given week (regression $R^2 = 0.01$ and 0.02,

TABLE 1. Overall recapture rate for adult *Polypedates leucomystax* at Sakaerat, Thailand, between 25 April and 4 September 2005.

	Number of recaptures				
	0	1–2	3–5	6–10	11+
Males	44	52	39	27	12
Females	22	8	0	1	0

respectively). Time to metamorphosis for tadpoles in basins with constant water levels was 41.66 ± 0.35 days and size (SVL) at metamorphosis was 19.40 ± 0.16 mm (mean ± SE).

I recorded several different call types. The most common was a single note ("normal") followed by 0–3 lower notes. Males also produced a "wreh-eh-eh" akin to a drawn out croak ("staccato"), a cackling sound ("cackle"), and a chuckle or laughing sound ("bark"; Fig. 4). These corresponded to call elements recorded in western Thailand (Christensen-Dalsgaard et al. 2002). All call elements were heard to be combined in various ways to create a complex call repertoire (Fig. 4). I analyzed call parameters of only the most common type of call, as this is believed to be the mating call (Christensen-Dalsgaard et al. 2002). Dominant frequency was 1197.1 ± 183.5 Hz, call duration was 58.5 ± 5.4 ms, pulse number (pulses/call) was 4.2 ± 0.3, and pulse rate (pulses/second) was 72.8 ± 4.2.

Discussion.—I report several new findings regarding the reproductive demography and behavior of *P. leucomystax* from Sakaerat, Thailand. First, both the mean and the maximum SVL of *P. leucomystax* at Sakaerat were larger than the maximum SVL of *P. leucomystax* in Borneo (Inger and Stuebing 1997: male maximum SVL, 50 mm; female maximum SVL, 75mm). The larger body size at higher latitudes is not surprising since many amphibians have been shown to follow Bergmann's Rule (Ashton 2002). Second, recapture rate for males was high, as was site fidelity (percentage of males only encountered within 20 m of their original capture point). This could indicate that males of this population are territorial. Christensen-Dalsgaard et al. (2002) frequently observed vocal interactions between males, in one case leading to wrestling between males. Although I never observed such interactions in the Sakaerat population, such interactions may also be indicative of territoriality. Although the number of new individuals found per search night was relatively low, it represented nearly a quarter of the total observations per search night. One possibility is that these individuals were present but not found during previous searches, but it is also possible that new individuals were constantly entering the local population.

Geographic variation in clutch size across the range of this species is uncertain. Although most reports on clutch size of *P. leucomystax* give only ranges and not mean values, Berry (1964) reported a mean clutch size of 315 (range 270–373) in Singapore, which is smaller than that found at Sakaerat (454). However, the range of clutch sizes at Sakaerat (230–804) overlapped with clutch size ranges from Borneo (150–900, Malkmus et al. 2002) and the Philippines (150–900, Alcala 1962; Taylor 1921; Villadolid and del Rosario 1930), indicating that within-site variation may swamp variation between sites.

Lack of variation in clutch size over time is surprising, as other frogs in seasonal tropical environments have shown decreasing clutch sizes over the course of the rainy season (Lampert and Linsenmair 2002; Lips 2001; Spieler and Linsenmair 1997; Williamson and Bull 1995). This could be due to the different variabilities, durations, or severities of the rainy seasons of each study location. For studies showing a decrease in clutch size as the rainy season progresses, rainfall generally decreases over the course of the season. At Sakaerat, the rainy season typically has five months of consistent rainfall (about 100 mm/month April–August) and then one to two months of extremely heavy rain (400 mm/month in September–October). Given the relatively short time to metamorphosis (about 42 d in basins kept in a shade house at ambient temperature), this 5–6 month rainy season might allow tadpoles to reach metamorphosis before larval habitat dries, even if eggs are laid in September or October. Temporal variation in breeding times of *P. leucomystax* at this site may reduce competition for resources among tadpoles and increase survivorship to metamorphosis.

Time to metamorphosis (42 d) was one and a half times longer than the 28 d previously recorded at Sakaerat (Heyer 1973) but nearly the same as the 49 d in Kuala Lumpur, Malaysia (Yorke 1983). It is important to note that Heyer's (1973) values are from non-experimental settings, and differences may be due to water temperature, food availability, and food type. Time to metamorphosis in my study was faster than the 70 to 119+ days reported for Philippine populations (Alcala and Brown 1956), and size at metamorphosis was slightly larger than the 14–17.5 mm reported for Philippine frogs (Alcala and Brown 1956). As with body size and reproductive measures, these differences in time to metamorphosis and size at metamorphosis could be due to temperature and rainfall differences between study sites, or could reflect the unrecognized taxonomic differences within this species.

Call types and diversity are similar to those reported from western Thailand (Christensen-Dalsgaard et al. 2002). Multiple call types also have been reported from northern Thailand (Garcia-Rutledge and Narins 2001) and Vietnam (Trepanier et al. 1999) but calls of *P. leucomystax* in Peninsular Malaysia, Borneo, and Bali appear to be less diverse (Marquez and Eekhout 2006; Matsui et al. 1986; Sanchez-Herriaz et al. 1995). A detailed summary of known call parameters from across the range of this species is given by Sheridan (2008).

Differences in life history variables between central Thailand and other populations of *P. leucomystax* are not surprising. Several studies on temperate amphibians show variation in clutch size, egg size, time to metamorphosis, and size at metamorphosis across a species' range (Berven 1982; Bury and Adams 1999; Kaplan 1980; Meeks and Nagel 1973; Riha and Berven 1991). However, no consistent trends of increases or decreases in these traits across latitude emerge from published data on temperate species and in general, we are still unable to predict variation in reproduction across latitudes for tropical species. Detailed studies on the reproductive ecology and behavior of tropical species such as *P. leucomystax* illustrate variation in reproduction across the range of a tropical species, and provide a baseline against which future changes can be measured.

Appendix I

Detailed Description of Study Areas

Dry dipterocarp forest.—This area consisted of 20 cement cisterns located 1–5 m from the main road in the deciduous dipterocarp forest at Sakaerat. These cisterns are round, 0.75 m in diameter, 0.32 m deep, and held water at depths of 0.1–0.3 m during the study period. This area occurs between km 1 and km 2.7 of the station road, with km 0 located at the junction of Highway 304 and the station road (Fig. 1).

Dry evergreen forest.—This area consisted of 34 cement cisterns, 0.75 m in diameter, in the evergreen forest at Sakaerat. Water depths were not less than 0.25 m. Cisterns were 1–5 m from the main road, except for two cisterns located 10 and 20 m from the road. The evergreen forest extends west from km 3 along the station road (Fig. 1).

Tam Jong An (Cobra Cave Pond) .—This area comprised 70 m of an ephemeral stream that runs parallel to the main road through Sakaerat, about 700 m to the north of the main road in the evergreen forest. The western end of the area was a semi-permanent pool of water at the base of a 3 m waterfall. As the two years prior to the study year were drier than normal, rainfall was quickly absorbed by the ground, the stream was not flowing during the study period, and the pool shrank from 4 x 20 m, to 3.5 x 12 m. Water in the remaining 65 m of stream bed was restricted to small ephemeral pools in rock crevices. The stream was bounded on the north and south by steep banks about 6 m apart. Note that the first date this area was sampled was 9 May 2005.

Dam Pond.—This area was an ephemeral pond covering approximately 75 m^2 created by a 5 m dam located approximately 100 m north of the main road near the km 5 marker (distance measured from Highway 304 along the main road through Sakaerat) in evergreen forest. The bottom of the pond was covered with herbaceous vegetation during this study period and contained standing water on only 2 survey nights. No eggs were

ever found on this transect, but amplectant pairs were found twice. This is not the same area as the "dam stream pond" referred to in Heyer (1973).

Tai Yee Pun (Thai Japanese ReAfforestation Project) .—This area was separated from those detailed above by ca. 7 km, and was a cleared area used as a plant nursery, ca. 120 m on a side. There were 20 cement cisterns 0.8 m in diameter along the road, and four 15 x 25 m nurseries covered by shade cloth. Two nurseries contained 6 rectangular 0.8 x 2 m cisterns 1m deep, with variable volumes of water. Depth of water in these cisterns varied between 0.1–1 m. A third nursery had four of these cisterns and the fourth nursery had four standard 0.75 m round cisterns. Note that the first day this area was sampled was 25 May 2005.

"Rarity" and "commonness" is more of a perception than a reality for some species. If one were to conduct a visual sampling of a cryptically colored species and compare it with that of a more conspicuous, non-camouflaged species of the same general size, the results might be very different, even if both species had the same absolute population density. In the same way, quiescent sit-and-wait predators may be more easily overlooked than similarly colored species of the same size that actively forage and attract attention because of their movement. This property of human visual perception can lead to erroneous assessments of densities, assemblage structure, and community dynamics by underestimating the relative importance of cryptic or secretive components of the fauna. General hand-collecting is especially prone to this source of error. Some other methods, such as pitfall traps that discount human visual acuity and discrimination, are more accurate by not being influenced by visual properties, but are biased in favor of selectively capturing the more active species and underestimating secretive ones. Even plot sampling can be highly inaccurate and numbers underestimated if the plots are small or unfenced and unless special measures are taken to prevent escapes or immigration (Heatwole 2008). Heatwole and Sexton (1966) devised a method of fenced plots, subsequently refined by Rodda et al. (2001a) and Heatwole (2008), that improves on other plot methods by completely censusing animals of all ages, including eggs, i.e., all individuals are found.

The present paper reports on a census of a small, Southeast Asian, forest-floor skink, *Sphenomorphus tridigitus* (Bourret 1939), using this method of fenced plots. This "rare" species was previously known from only four specimens. It was originally described on the basis of a single specimen in a poor state of preservation found dead on a road at Bach Ma, Thua Thien-Hue Province, Vietnam (Bourret 1939). Greer et al. (2006) redescribed the species from a second specimen found "at day, hidden inside a log lying on grass near a small creek in an open forest" at 1200–1250 m elevation on the Bolaven Plateau (="Boloven Highlands") in Champasak Province, Laos. Bain et al. (2007) reported on two additional specimens that were collected in pitfall traps, one at 940 m elevation and one at 1470 m elevation, on Mt. Ngoc Linh, Tra Don Commune, Tra My District, Quang Nam Province, Vietnam.

The present study took place at three sites (15°02'48"N 106°10'45"E, 400 m elev.; 15°04'37"N 106°08'15"E, 1000 m elev.; 15°03'55"N 106°13'03"E, 1200 m elev.) on the Bolaven Plateau in the Dong Hua Sao National Protected Area (formerly National Biodiversity Conservation Area), Pakxong District, Champasak Province, Laos during 10–25 September 1999. Eight plots, each 10 m x 10 m, were fenced by mosquito netting 1 m high with the bottom edge buried in a trench, and then the low vegetation, litter and wood removed down to mineral soil by Heatwole's (2008) method. Specimens of *S. tridigtus* collected in the study were deposited at The Field Museum (FMNH 258772–98, 258824–40, 258843–63, 258914–18, 258929–38). These specimens fully agree with the detailed redescription of the species by Greer et al. (2006), including discrepancies from the type. Like the specimens of Greer et al. (2006) and Bain et al. (2007), ours have a frontonasal scale with two separated prefrontals and the nasal and first supralabial are fused (erroneously called the "first infralabial" by Greer et al. [2006] and repeated by Bain et al. [2007]), and the loreal and the

preocular are not fused. The specimens in our series have snout-vent length from 16.5 mm (hatchling) to 43.6 mm (largest adult). The eggs, collected from under leaf litter in the plots (see Table 1), are creamy-white to yellow, oval, and leathery and average 8.2 mm long by 4.8 mm wide (after preservation in 10% formalin). Most have a small, purplish-black spot visible through the eggshell. A fully developed skink is visible through the eggshell of two eggs (FMNH 258918). A baby skink hatched from one egg (FMNH 258917) immediately upon immersion of the egg in formalin in the field, making identification unambiguous. Animals with regenerating tails accounted 5.5% of the specimens captured.

The plot results for *S. tridigitus* are summarized in Table 1. All individuals and eggs from the census plots were found under leaf litter. Six of the eight plots (75%) contained this species and it was clear that abundance was related to elevation. Intensive searching over 16 days (10–25 September 1999) at these sites by the authors and two camp assistants (and others sporadically) in the conventional way yielded only two individuals of this species, one under leaf litter when clearing a campsite and the other inside a rotten log. Thus, by the standard methods of expeditionary field surveys, this species would have been considered rare at the study site. In fact, it was the most abundant reptile in the area. Without the plot method the small numbers of individuals otherwise obtained would not have revealed this. No animals were found at low elevations but they were relatively abundant at 1000 m. Population density was lower again at 1200 m. Hence, this species is most abundant at mid-elevations.

At 1000 m on average there was one egg for every 3.5 adults, whereas at 1200 this value dropped to one egg for every 8.75 adults suggesting either that reproductive rate was much lower at the higher elevation, or that the reproductive season differed between the two sites.

This species, rather than being an insignificant rarity, is abundant at higher elevations on the Bolaven Plateau, where it accounted for 86% of the total individuals of the forest-floor lizards and frogs (6 species; snakes inadequately sampled) at 1000 m and 57% of the individuals of forest-floor lizards and frogs (8 species) at 1200 m. At a lower elevation on the plateau where *S. tridigitatus* was not present, it was replaced by a similarly small skink in the *Scincella reevesi* complex (mean density: 0.05/m^2; 64% of total individuals of the forest-floor frogs and lizards; four species). These two skinks probably play an important role in the dynamics of the forest floor community as significant predators upon small invertebrates and as food for various snakes.

Rodda et al. (2001a,b), using a censusing technique similar to the present one, also found unexpectedly high densities of some small reptiles and it is likely that many small forest-floor lizards are far more abundant than they appear to be. Estimates of density are used in studies of population biology and structure of assemblages and often play an important role in decisions about conservation. Much of the previous literature, even that based on fenced plots, probably contains serious underestimates and needs to be reassessed by research using more refined, fenced-plot techniques.

Acknowledgments.—Fieldwork was conducted under the auspices of the Wildlife Conservation Society/Division of Forest Resource Conservation Cooperative Program. Specimens were exported to the Field Museum of Natural History under permits issued by the Ministry of Agriculture and Forestry, Vientiane, Laos. This research was funded by the National Geographic Society, the Wildlife Conservation Society, the John D. and Catherine T. MacArthur Foundation and the North Carolina Agricultural Research Service.

The canopy strata of tropical forests are one of the remaining unexplored biotic frontiers. Canopy research is a relatively new discipline facilitated by recent methodological advances in canopy access techniques (Basset et al. 2003b). Forest canopies are among the most species-rich terrestrial habitats on earth, supporting approximately 40% of known extant species and estimated to hold up to 50% of the earth's biodiversity (Basset et al. 2003b; Mitchell et al. 2002). The ecological role of amphibians and reptiles in forest canopies is mostly unknown. Thus far the research focus has been on arthropods, birds, mammals, plants and ecological processes; investigations of canopy herpetofauna have only recently been documented (De Vries et al. 1997; Guayasamin et al. 2006;

Schiesari et al. 2003). Kays and Allison (2001) reviewed published ecology and study methods for arboreal tropical forest vertebrates and found amphibians and reptiles to be grossly understudied compared to mammals, primarily due to their cryptic habits and sampling difficulties. Of 752 articles on tropical forest arboreal vertebrates published between 1988 and 1998 only 4% focused on reptiles and amphibians, with the majority of those covering reptiles (Kays and Allison 2001). While many studies report arboreal occupancy by an extensive number of amphibian species, few have documented ecological characteristics besides presence/absence data based on calling males and new species descriptions (Duellman and Trueb 1986; Guayasamin et al. 2006; Schiesari et al. 2003). Most data for arboreal amphibians were obtained through collection and observation during reproduction of those species that descend from the canopy to breed in water bodies at the forest floor level (Duellman 1978; Duellman 2005; Ron and Pramuk 1999). Standard survey techniques for amphibians, such as those at breeding sites, only encompass a small stratum (~2 m vertical height) of forest diversity (McCracken et al. 2007). Amphibians that specialize within the upper canopy remain mostly unaccounted for as a result of this limited vertical sampling bias (Guayasamin et al. 2006). More practical methods for studying canopy amphibians and reptiles is a high priority to facilitate the need for more survey and natural history work (Kays and Allison 2001).

A component of neotropical rainforest canopies that provide rich fauna microhabitats are the phytotelmata, defined as plants or parts of plants which hold rainwater (e.g. bromeliads, fruits, inflorescences, palm fronds and tree holes). In some tropical locations the availability of this habitat for aquatic organisms is up to 50,000 liters per hectare, literally a "wetland in the sky" (Kitching 2000; McCracken and Forstner 2006). In particular, epiphytic tank bromeliads are capable of holding relatively large amounts of water and play a principal role as a "keystone resource" and microhabitat for invertebrates, vertebrates and other plants (Nadkarni 1994). Canopy bromeliad arthropod surveys have reported them as reservoirs of incredibly high biodiversity (Basset et al. 2003a; Kitching 2000). Typically, tank bromeliads occur in the upper canopy and overstory trees of lowland rainforest at vertical heights between 5–45 m. Bromeliads normally range in number of individuals from ~5 to >150 on a single tree. Herein, we describe a technique for canopy bromeliad patch sampling of herpetofauna in lowland neotropical forests which is similar to those used in other canopy research disciplines but has not been documented for herpetofaunal investigations.

Methods.—Bromeliad patch sampling was conducted during 2004 and 2006 at the Tiputini Biodiversity Station (TBS)–Universidad San Franciso de Quito (USFQ), Orellana Province, Ecuador (00.63847°S, 076.14908°W, 217 m elev.). The vegetation type of the site has been defined as Amazonian Evergreen Lowland Forest (Palacios et al. 1999). Sampling units consisted of five bromeliads from each of 16 trees for a total of 80 bromeliads sampled. A tree was not sampled if less than 15 bromeliads of any species to be sampled were present to ensure continued persistence of the bromeliad community. Host trees were measured for diameter at 1.5 m above ground, height using a clinometer, and canopy cover using hemispherical photography with the Gap Light Analyzer (GLA) software. A leader line was positioned in the tree using a large slingshot (Sherrill™ Big Shot) which enables setting lines at 30+ m. The canopy was accessed using single-rope technique, which should only be performed by trained and experienced individuals (Fig. 2d). The lowest and highest elevation bromeliads were sampled with the remaining three sampled at estimated even intervals in between (Fig. 1). Before removal of each bromeliad a wide-angle photograph was taken and the following variables collected: elevation, ambient air temperature, relative humidity, barometric pressure, water temperature and pH are measured inside one of the outer leaf bracts, and a 50 ml water sample is collected by siphon. Ambient air temperature, relative humidity and barometric pressure were also collected at 1.5 m elevation. The bromeliad was removed by holding several leaves at the tips in one hand and cutting its base support stem with a pruning saw. The response of most animals is to retreat into the bromeliad bracts and therefore alleviates loss of specimens due to escape. The bromeliad was placed in a 55 gal. plastic bag with minimal disturbance, sealed, and placed in a tarp connected to a rope that is threaded through a carabiner on the climbers harness and the other end held by a ground support person. It was then gently lowered to the forest floor by the ground support person. Another photograph was taken of the site where the bromeliad was removed. After removal of the five bromeliads, a herbarium sample was collected from the tree to confirm identification and deposit in a herbarium. Bromeliads were processed at camp in a screen tent to prevent escape of animals (Fig. 2c). Bromeliad water was strained through a 1 mm mesh screen to separate arthropods, leaf litter, and detritus. Water volume was measured with a graduated cylinder. Bromeliads were measured, number of leaves counted, and photographed including a meter stick for scale reference (Fig. 2a, b). Individual leaves were removed to facilitate collection of herpetofauna, which were temporarily stored in bags

for further processing. Herpetofauna species were photographed, measured and weighed. Blood or tissue samples were collected and stored in blood storage buffer or 95% ethanol, respectively. Animals were euthanized in 10% ethyl alcohol or by ventral application of 20% benzocaine (Orajel®) and preserved using 10% formalin before being transferred to 70% ethyl alcohol for storage.

Results.—In 2004, eight trees were surveyed for a total of 40 bromeliads sampled. Three species of bromeliads were sampled: 20 individuals of *Aechmea zebrina*, 17 of *Aechmea* sp., and three of an unidentified tankless bromeliad. In 2006, eight trees were surveyed for a total of 40 *A. zebrina* bromeliads sampled as part of a current study. Bromeliads were collected at elevations of 5.7–38.0 m (mean 27.0 ± 6.2 m) above ground. *Aechmea zebrina* bromeliads were 58.5–125.0 cm (mean 79.9 ± 13.9 cm, N = 40) tall and 54.0–147.5 cm (mean 89.5 ± 22.2 cm, N = 40) in diameter, *A* sp. bromeliads were 32.0–58.0 cm (mean 47.2 ± 9.7 cm, N = 17) and 54.0–94.0 cm (mean 66.8 ± 12.6 cm, N = 17) in diameter, and the unknown tankless bromeliads were 41.0–47.0 cm (mean 43.8 ± 3.1 cm, N = 3) and 33.0–43.0 cm (mean 37.3 ± 5.1 cm, N = 3) in diameter.

Thirty-four adults, 10 juveniles, 15 tadpoles, and 17 eggs of anurans representing at least four species were collected during the two survey periods. The identified adult and juvenile species included *Dendrobates* (*Ranitomeya*) *ventrimaculatus*, *Eleutherodactylus* (*Pristimantis*) *aureolineatus*, *Eleutherodactylus* (*Pristimantis*) *waoranii*, and *Osteocephalus taurinus*. Eight of the tadpole specimens were easily identified as *D. ventrimaculatus* due to their advanced stages of development. The remaining tadpole specimens are to be identified using morphological and/or molecular techniques. One gecko, *Thecadactylus rapicauda*, was collected in an *A. zebrina* in 2006. Only one anuran was observed jumping from a bromeliad during removal and was visually identified when it landed on a nearby bromeliad before retreating into the leaf bracts.

Of the three bromeliad species, no anurans were found in the three tankless bromeliads, nine tadpoles of *D. ventrimaculatus* and three adult *E. waoranii* in five *Aechmea* sp., and the remainder in 26 *A. zebrina* (65% of *A. zebrina* sampled had anurans). All anurans were collected in bromeliads between 20.0–36.0 m (mean 28.3 ± 5.3 m) above ground.

Discussion.—Visual encounter surveys, focal point observations, and inspection of individual bromeliads along a 100 m-long canopy walkway and two ~40 m high observation towers built around emergent trees at TBS–USFQ revealed 13 species of anurans; these surveys were conducted 3–4 times a year from 1998 to 2001 dur-

ing the morning, afternoon, and night for 4–5 days duration (Cisneros-Heredia 2003; D. F. Cisneros-Heredia, pers. comm.). During one week in May 2002 canopy searches targeted at calling anurans were conducted using tree-climbing spurs at the Yasuni Scientific Research Station–Universidad Católica del Ecuador and resulted in the discovery of six anuran species occupying canopy habitat (S. Ron, pers. comm.). Canopy bromeliad patch sampling revealed a minimum of four species and the additional species *E. waoranii* (McCracken et al. 2007). Results from our surveys contributed significantly to the new species description for *E. aureolineatus* and a manuscript on the reproductive ecology and behavior; they are wholly responsible for the new species description of *E. waoranii* (Guayasamin et al. 2006; McCracken and Forstner 2006; McCracken et al. 2007). Three other species found during these canopy surveys are newly described since 1999, demonstrating the value of such research techniques (Guayasamin et al. 2006). The potential for the discovery of additional new species and collection of detailed ecological data at other sites is evident in the fact that our surveys and the previous canopy surveys represent a limited sampling effort at two sites within close geographic proximity (~28 km) and similar habitat structure.

The technique provides a labor intensive, but successful, method for surveying the otherwise inaccessible microhabitats of the upper forest canopy strata herpetofauna. While our bromeliad patch sampling technique recovered less than a third of the number of species collected during the canopy walkway/tower surveys it represents a much less intensive sampling effort. Our sampling focused on the specific microhabitat provided by bromeliads, of which we only investigated three species. Our results indicate that the largest tank bromeliad in our surveys, *A. zebrina*, had the greatest occurrence rate, with 65% of those sampled having anurans present. The use of canopy bromeliad patch sampling is also supported by the limited availability of canopy walkways and towers for research in Amazonia, and the financially prohibitive construction costs of such infrastructure for most research projects. Canopy bromeliad patch sampling can be employed anywhere the forest is accessible and facilitates the collection of independent replicate sampling units with associated biotic and abiotic factors for the analysis of ecological correlates of species diversity and abundance in a robust sampling design. Our current study targets a species specific (*A. zebrina*) tank bromeliad microhabitat, but the technique may be applied to other species and microhabitats (e.g. tree holes/cavities) within the canopy. The technique may also be used to survey other forest canopies and their specific microhabitats.

Fauna of forest canopy habitats are at risk due to high rates of deforestation and habitat fragmentation, which are primary reasons for the rapid decline in amphibian populations worldwide with nearly one-third of all amphibians being threatened and at least 43% declining in population size (IUCN et al. 2006). The rapid exploitation of natural resources is having a profound effect on the rainforests and its inhabitants of the Ecuadorian Amazon. Yet, little is known about the effects of canopy biota loss. Epiphytes are considered hypersensitive to climatic conditions, requiring the very conditions they promote for existence (Benzing 1998, 2000; Hietz 1998). This hypersensitivity makes them particularly susceptible to forest microclimate changes as a result of anthropogenic disturbance, making epiphytes suitable as a bioindicator of diversity and forest ecosystem functions (Benzing 1998; Brighigna et al. 2002; Hietz 1998). Loss of epiphyte diversity will degrade all biodiversity within inclusive ecosystems by causing shifts in faunal resource availability, nutrient budgets and cycling, system energetics, and hydrology (Benzing 1998). Amphibians may be considered a vertebrate counterpart to epiphytes as bioindicator species and their utilization of epiphytic tank bromeliad habitat provides the researcher with a unique system for monitoring anthropogenic disturbance in forest canopies. Bromeliad patch sampling surveys are essential to documentation of the faunal diversity in neotropical forest canopies and promoting the conservation of these important "wetlands in the sky" (McCracken and Forstner 2006).

Acknowledgments.—This research was funded by a National Science Foundation Graduate Research Fellowship to S. F. McCracken, the TADPOLE Organization, Austin, Texas in conjunction with private donors, and Texas State University–Department of Biology. We thank the following: staff at the Tiputini Biodiversity Station–Universidad San Francisco de Quito, especially Jaime Guerra, David Romo, Kelly Swing, and Consuelo de Romo for coordinating logistical support; David Romo for help obtaining research, collection, and export permits; Bejat McCracken for photography, field work assistance, and unwavering support; Paul Herbertson, Robert Winters, and Tana Ryan for field work assistance; James R. Dixon of Texas A&M University and Mark Mulligan of King's College London for continued support; anonymous reviewers and the editors for their review, comments, and suggestions used in the manuscript. Specimens were collected under permit numbers 006-IC-FA-PNY-RSO and 012-IC-FA-PNY-RSO, and exported under permit numbers 001-EXP-IC-FA-RSO-MA and 005-EXP-IC-FA-RSO-MA issued by the Ministerio del Ambiente, Ecuador. Research conducted in accordance with Texas State University Institutional Animal Care and Use Committee protocol #06-01C694AF.

The terrestrial ecology of many amphibians is poorly known compared with the aquatic stages (e.g., Regosin et al. 2003). Although advances have employed radiotelemetry on terrestrial adults (e.g., Hodgkison and Hero 2001; Watson et al. 2003), the size and battery life of transmitters are limitations on the use of radiotelemetry for smaller amphibian species and life stages. Other approaches for following small amphibians have included powder tracking, radioactive tags, and harmonic radar diodes, but each of these techniques has significant limitations (Heyer et al. 1994; Langkilde and Alford 2002).

Passive integrated transponders (PIT tags) overcome many limitations of these other techniques. PIT tags are small, glass-encased electromagnetic coils with a microchip containing a 10-space unique alphanumeric code that is emitted at a radio frequency (typically 134.2 kHz) when the coil is activated. PIT tags are easily applied and relatively benign to the tagged animal, provide a unique and essentially permanent mark, and can be cost-effective (Arntzen et al. 2004; Gibbons and Andrews 2004; Ott and Scott 1999). As a result, PIT tags have been increasingly used for marking fish, amphibians, reptiles, and other animals for demographic and behavioral studies (e.g., Camper and Dixon 1988; Kurth et al. 2007; Reaser 2000; Rowe and Kelly 2005; Sinsch 1992). Usually, PIT tag detection relies on the physical recapture of the tagged organism because the tag needs to be within range (usually ~ 0.3 m) of an antenna to transmit the alphanumeric identification code to the transceiver (see review by Gibbons and Andrews 2004). Portable antenna and transceiver systems (PIT-packs) are a new approach to locating and identifying a tagged organism without physical recapture, thereby minimizing associated disturbances (Hill et al. 2006; Kurth et al. 2007; Zydlewski et al. 2001).

We evaluated a PIT-pack as a tool to locate and identify confined individuals of two pond-breeding amphibian species, recently metamorphosed *Rana pipiens* (Northern Leopard Frogs) and adult *R. sylvatica* (Wood Frogs). We evaluated the detection range of the PIT-pack using PIT tags alone and the detection probability of frogs implanted with PIT tags and held in terrestrial enclosures. We used the PIT-pack to identify breeding pairs in a small vernal pool and collect information on the breeding ecology of *R. sylvatica*. In addition, we evaluated three surgical implant locations and PIT-tag retention in recently metamorphosed *R. pipiens*.

Methods.—The PIT-pack consisted of a battery-powered Destron-Fearing transceiver (Model FS 2001A-ISO; Digital Angel Co., St. Paul, Minnesota, USA) and custom-built antenna. The antenna head was constructed in an airtight oval (0.20 × 0.25 m) with 1.27-cm schedule 40 PVC. The antenna consisted of 20-gauge multi-strand wire wrapped 26 times through the PVC frame until an inductance of approximately 425 μH was reached. Capacitors were attached to the antenna lead cable and enclosed in the PVC, fixing the capacitance at ~ 3300 pF. Fine-scale tuning was achieved with a 400–1600 pF variable capacitor. The head of the antenna was mounted on an adjustable 1.5-m long handle at an angle of ~ 120° (Fig. 1). The instrument was tuned in water or air immediately prior to use at each site to maximize current at 3.0 to 3.3 Amps. In theory, changes in soil or water density and chemistry can affect the electromagmetic field generated by the antenna, and consequently it is necessary to tune the antenna prior to use in the medium (i.e., air or water) in which it will be used to achieve the maximum detection range. The PIT-pack is light (3.1 kg) and portable in the terrestrial environment (Fig. 1), but the transceiver is small and low-powered. Heavier equipment with a larger antenna head size (e.g., 0.55 × 0.40 m and 19.3 kg in Hill et al. 2006) would probably have greater detection ranges but would sacrifice the convenience of the smaller unit (Kurth et al. 2007; Zydlewski et al. 2001). We used 12-mm PIT tags (134.2 kHz ISO tag; Model TX1411SST, Digital Angel Co., St. Paul, Minnesota, USA) in all experiments because the small size of our study frogs. Tag size may contribute to performance, and larger tags may increase the detection range for other applications (Hill et al. 2006; Roussel et al. 2000).

FIG. 1. Using a PIT-pack to search for PIT-tagged, recently metamorphosed *Rana pipiens* in a terrestrial enclosure in a three-year old clearcut in Maine, USA. We held the transceiver in a shoulder bag, and constructed the antenna using a modified forearm crutch for ergonomics. We varied the angle of the antenna to increase the detection probability as we searched for concealed frogs, and an audible beep from the transceiver alerted us to detection of a tag. Photograph by Valerie Moreau.

Prior research with larger 23-mm tags and more powerful readers reported detection ranges of 30–38 cm in air and 60–91 cm in water (Cucherousset et al. 2005; Hill et al. 2006). With a blind observer, we evaluated the PIT-pack detection range for 30 PIT tags in 30 mL polyethylene vials in each of two soil types commonly found in Maine, USA, forests (N = 60 total tags). We visually evaluated each area and assessed one to be predominantly glaciomarine hydric soils found in wetlands and the second to be predominantly well-drained till soils found in uplands (Natural Resources Conservation Service, 1963). One observer dispersed PIT tags in a 16 m^2 area (4 × 4 m) at depths ranging from the soil surface to 76 cm by driving a measured metal rod to the desired depths in the soil. A second observer, naive to the location and number of tags, searched the area with the PIT-pack by walking in a systematic zig-zag pattern through the area and making three passes through the area to find the tags. The first observer, who placed the tags, recorded the number and identity of the tags found on each pass. The first, informed observer then made one pass though the area and attempted to detect tags that were missed using the PIT-pack.

We collected recently metamorphosed *R. pipiens* and adult *R. sylvatica* from the University of Maine's Dwight B. Demeritt and Penobscot Experimental Forests (Penobscot County, Maine, USA, 44°50'N, 68°35'W) with hand capture and pitfall traps in August 2006. We housed all frogs in 125 L plastic tanks or 38 L glass aquaria in small groups (20 metamorphs and 5 adults) for 1–16 days prior to experiments (described below). Each container had leaf litter for cover, holes in the top, and a wet paper towel on the bottom to maintain moisture. We fed captive frogs crickets *ad libitum*. We measured (snout–vent length [SVL], mass) and marked each animal individually with a PIT tag.

We surgically implanted PIT tags sub-dermally as recommended for small amphibians (Ott and Scott 1999). We anesthetized all frogs using 0.5 g/L MS-222 (tricaine methanesulfonate; Sigma Aldrich, St. Louis, Missouri, USA) in well water prior to surgery. We lightly anesthetized the frogs to minimize mortality associated with small frogs (e.g., Cecala et al. 2007), and held frogs in anesthesia only until they lost their righting response but remained responsive to touch (< 15 min in most cases). We made a 2-mm long incision with a sterile, single-use blood lancet (Propper Mfg. Co., Long Island City, New York, USA). To cut only the skin, we placed the blood lancet at an acute angle to the body of the frog and lightly pressed it into the skin until the skin began to fold upwards. We continued to apply pressure until we pierced the skin. After making the incision, we slipped a sterile PIT tag through the

incision, and placed one drop of Bactine (Bayer Co., Pittsburgh, Pennsylvania, USA) on the wound to sterilize the incision and promote healing. Frogs recovered from surgery for 6 hours before release, and we assessed tag retention and the condition of the wound after the frog recovered.

We conducted a two-week laboratory trial to determine the best position for PIT tag placement in small ranids. Three positions (scapula insertion, pubis insertion, ilium insertion) were tested in recently metamorphosed *R. pipiens* (N = 20 for each position). For scapula insertion, a longitudinal incision on the dorsum was made above the scapula ~ 3 mm posterior to the eye and ~ 2 mm medial to the tympanum. For pubis insertion, a lateral incision was made ~ 2 mm anterior to the posterior end of the urostyle. For ilium insertion, a longitudinal incision was made ~ 1 mm anterior to the anterior end of the ilium and centered on the dorsum. The frogs used in the experiment were 34 ± 1 mm (mean ± SE; range 31–38) SVL and weighed 4.0 ± 0.3 g (range 2.8–6.1). Frogs were checked twice daily for tag retention and healing of the surgical wound.

Based on the results of the retention study, we PIT tagged (scapula insertion) 50 adult *R. sylvatica* (26 males, 24 females; 46 ± 1 mm SVL, range 41–55 mm; 14.5 ± 0.5 g, range 10.1–24.9 g) and 52 recently metamorphosed *R. pipiens* (37 ± 1 mm SVL, range 31–48; 4.5 ± 0.2 g, range 1.0–8.7 g) in August 2006. Tagged frogs were placed into uninhabited 3.8 × 3.8 m (14.4 m^2) terrestrial enclosures constructed 15 months prior to data collection in an unharvested forest (unharvested), a forest partially harvested to 50% crown closure (partial), and a 3-year old clearcut with coarse woody debris removed (removed) on the Dwight B. Demeritt and Penobscot Experimental Forests (see Patrick et al. 2006 for a description of the sites). Enclosure walls were 1.2 m tall galvanized steel hardware cloth (3.2 mm square mesh; TWP Inc., Berkeley, California, USA) supported with wooden garden stakes. Enclosure walls were buried 20–30 cm in the ground and bent 10 cm at the top toward the inside of the pen to prevent escape of animals.

We stocked terrestrial enclosures with *R. pipiens* metamorphs and *R. sylvatica* adults. *Rana pipiens* metamorphs were stocked to three enclosures: one enclosure in the removed treatment at a density of 12 per enclosure (0.83 m^{-2}), one in the removed treatment at a density of 20 per enclosure (1.39 m^{-2}), and one in the unharvested treatment at a density of 20 per enclosure (1.39 m^{-2}). We were unable to capture enough *R. pipiens* metamorphs at our study sites to replicate each density and treatment combination. For *R. sylvatica* adults, we stocked each of 10 enclosures at a density of five per enclosure (0.35 m^{-2}): five enclosures in the partial treatment and five in the unharvested treatment. We located *R. pipiens* metamorphs every three days during 23 August – 7 September 2006 and once weekly thereafter through 11 October (the end of the growing season in central Maine). We located *R. sylvatica* adults once weekly from 26 August to 27 September 2006. We removed dead frogs and did not include them in subsequent detection probability calculations.

Lastly, we captured (drift fences and by hand) 139 adult *R. sylvatica* (61 females, 78 males) returning to breed at a single, ~ 80-m^2 vernal pool on the University of Maine's Dwight B. Demeritt Experimental Forest in April 2007. Each frog was PIT tagged (scapula insertion), and held in captivity for < 9 h prior to release at ~ 1 h before sunset. Nightly during 22 April – 2 May we located pairs in amplexus with a spotlight and by scanning the surface of the water with the PIT-pack. We attempted to identify both members of each located pair with the PIT-pack without disturbing the frogs. We relocated the pair visually and with the PIT-pack until the female oviposited. Each morning we counted the number of fresh egg masses in the pond. We conducted all statistical analyses in SAS (SAS Institute, Cary, North Carolina, USA) with α = 0.05.

Results and Discussion.—Our mean detection probability was 0.65 ± 0.14 (± 95% confidence interval), and we detected 100 ± 0% of the tags at 13 cm and 33 ± 7% of PIT tags at 43 cm in the soil (Fig. 2). The informed observer (i.e., who knew the location of the tags) detected a higher proportion of tags in a single pass (0.76) than the blind observer (0.61 ± 0.03; range 0.57–0.67) did in three passes. This higher success in detecting tags is probably due to increased effort in an area known to have a tag versus the systematic pattern employed by the blind observer. Subtle changes in antenna orientation associated with concentrated effort in one area can change detection success without a change in detection range. The antenna is most effective at detecting a tag if the tag is perpendicular to the face of the antennae (Cucherousset et al. 2005).

No frogs died during the two-week tag retention experiment. Tag retention after two weeks was highest with the scapula insertion technique; all *R. pipiens* retained their tags. Retention also was high with ilium insertion (90%), but retention with pubis insertion was poor (55%). All tag loss occurred before the incision healed, generally in < 6 days during these laboratory trials. The scapula and ilium insertion techniques will probably result in high tag retention rates in other similar sized frogs, although retention rates are important to quantify for any field study.

The proportion of recently metamorphosed *R. pipiens* detected with a PIT-pack was not affected by harvesting treatment or density, and the proportion detected in the three terrestrial enclosures remained at 1.00 throughout the study (Fig. 3). The proportion of adult *R. sylvatica* detected remained high (> 0.90) until the first time the minimum daily temperature (MDT) was < 0°C, but declined over subsequent surveys. Because the proportion detected

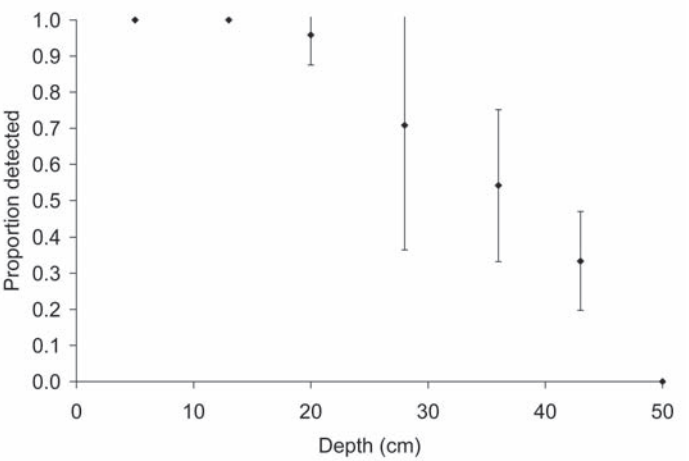

FIG. 2. Mean (± 95% confidence interval) proportion of PIT tags detected per depth in the soil using a PIT-pack in two 16 m^2 areas. Each depth had six tags available for detection and means were calculated from all four passes with the PIT-pack. All depths 50 cm were lumped.

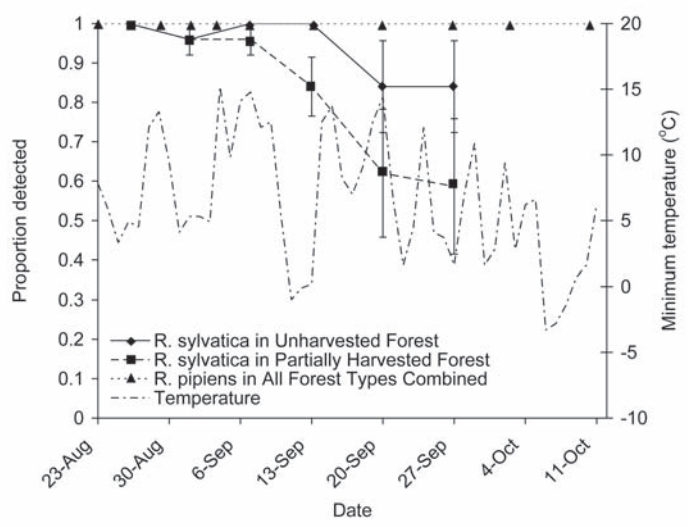

FIG. 3. Mean (± SE) proportion of PIT-tagged frogs detected with a PIT-pack in 14.4-m^2 terrestrial enclosures in unharvested forest (recently metamorphosed *Rana pipiens*: one enclosure with 20 frogs; adult *R. sylvatica*: five enclosures with five frogs each), a forest partially harvested to 50% crown closure (adult *R. sylvatica*: five enclosures with five frogs each), and a 3-year old clearcut (recently metamorphosed *Rana pipiens*: one enclosure with 20 frogs and one enclosure with 12 frogs) in Maine, USA, in 2006. Data for the three enclosures containing *R. pipiens* are presented together because the proportion of frogs detected was always 100%. Proportion of frogs detected dropped for *R. sylvatica* after the minimum daily temperature fell below 0°C for the first time.

remained high until 11 October 2006 for the aquatic hibernator *R. pipiens* (Rorabaugh 2005), we speculate that adult *R. sylvatica* began to enter subterranean hibernacula (Redmer and Trauth 2005) in refugia below our detection range with the PIT-pack, and thereby reduced the proportion of frogs detected. We are confident that the enclosures were escape proof (only one of 1600 *R. sylvatica* and *Ambystoma maculatum* stocked into 64 enclosures in 2005 escaped; SMB and MLH, unpubl. data). Although the steel walls reduce detection range when the antenna is nearby, we detected adult *R. sylvatica* within ~ 5 cm of the fences at depths of 16 cm deep on 27 September.

A PIT-pack is a non-invasive method for locating tagged individuals, and this technique can make multiple recapture studies in confined areas more feasible. Most studies using terrestrial enclosures use destructive sampling (e.g., Rodda et al. 2001) or pitfall trapping to sample or census animals in enclosures (e.g., Bailey et al. 2004). With a PIT-pack, a user can repeatedly search an enclosure with minimal disturbance. Advantages of this technique for sampling enclosures are that it is relatively noninvasive, the user can search until all animals are detected, and detection probability should remain at 1.00 unless the study animal is likely to move below a depth of 13 cm (detection range of the PIT-pack; Fig. 2). The effectiveness of the PIT-pack would be limited for species that burrow deeper than 13 cm. For example, *Ambystoma maculatum* burrows up to 1.3 m in winter (Semlitsch 1983). In addition, some species may not be detected during some seasons. For example, *Spea multiplicata* burrows 1.3–10 cm deep in summer and up to 90 cm in winter (Rubial et al. 1969).

Two potential future applications for this technology are tracking in subterranean environments and tracking juvenile anurans. Anurans, especially bufonids (e.g., Eggert 2002), are known to use the subterranean environment as a refuge from thermal extremes and to conserve water (Duellman and Trueb 1986). Ranid frogs can dig their own burrows (Parris 1998), and many species use burrows excavated by other animals (e.g., Blomquist and Tull 2002; Lips 1991). However, the duration of time spent in the subterranean environment is not well studied, and PIT-tag telemetry could be used to non-invasively monitor amphibians in shallow subterranean habitats (see the study design of Quintella et al. 2005 for a possible method). A PIT-pack would be an effective technique for tracking burrowing species that use shallow burrows <

TABLE 1. Number of pairs of adult *Rana sylvatica* identified and observed ovipositing at a breeding pond in Maine, USA, in 2007; number of pairs disturbed with a PIT-pack prior to laying or identification of both individuals; additional pairs observed and not disturbed but both individuals were not identified or the pair was not observed ovipositing; and new egg masses observed the next morning. Males began calling on 16 April 2007, but females were not present until 22 April at which time we began nightly observations at this vernal pool.

Date	Pairs identified and observed ovipositing	Pairs disturbed	Additional pairs observed	New egg masses observed
22 April	0	0	0	0
23 April	0	0	0	0
24 April	16	4	3	17
25 April	2	0	0	2
26 April	4	2	2	4
27 April	0	0	0	0

13 cm deep (e.g., *Spea hammondii*; Morey 2005).

Juvenile survival and movement can be important factors in population persistence (e.g., Red-legged Frogs in Biek et al. 2002; Conroy and Brook 2003). For example, dispersal in most amphibian species probably occurs as juveniles (e.g., Berven and Grudzen 1990; Dole 1971). Survival and movement probably are quite different in many anuran species, and PIT-based telemetry could be used to improve knowledge about the ecology of juvenile and small adult amphibians. However, the applicability of PIT-tag telemetry to free-ranging individuals could be limited. The technique will probably work best with animals that have small home range sizes and are not likely to use the subterranean habitat deeper than 13 cm during the period of study. Searching the terrestrial habitat for moving individuals (e.g., dispersing juveniles) could be labor-intensive and thus costly and only generate low recaptures of marked animals (see Arntzen et al. 2004 for a detailed analysis of the use of PIT tags and associated costs of a capture-mark-recapture studies). For example, searching the 14.4-m^2 enclosures took 6 ± 4 (± SD) minutes with the 0.20 × 0.25 m head antenna across all forest types. In addition, dispersing or migrating animals can move relatively long distances in a short period when environmental conditions are conducive to movement (e.g., a warm, rainy night for pond-breeding amphibians in Maine, USA), which would necessitate more frequent relocation in these conditions.

We used a PIT-pack to non-invasively identify 40 pairs of PIT-tagged *R. sylvatica* in amplexus (Table 1), and relocate and monitor 25 of these pairs until the female oviposited. The number of pairs we identified and monitored until the female oviposited each night was highly correlated with the number of new egg masses in the pond the following morning (Pearson's correlation $r = 0.983$, $p < 0.0001$). This result indicates that we identified most of the frogs that successfully bred in the pond and the other 59 frogs we captured entering the pond did not successfully breed. In most instances where both male and female were identified, we were able to position the antenna underwater below the pair to read the female's tag. In seven instances, we were able to identify only the male because his PIT tag interfered with detection of the female's tag (Table 1, additional pairs observed column). We lost track of one pair prior to observing oviposition. The male stopped amplexus by releasing the female (Table 1, pairs disturbed column) when we placed the antennae near seven pairs. This disturbance typically occurred after we identified the male and moved the water and vegetation while moving toward the pair with the antenna to identify the female. We speculate that using a PIT-pack to identify breeding pairs of *R. sylvatica* was much less invasive than would be required using other techniques. Identifying animals marked with visual implant elastomer or toe clipping usually requires handling, and externally attached radio-transmitters can interfere with swimming and amplexus in some frogs (e.g., Muths 2003).

In summary, we successfully used PIT-tag telemetry to track recently metamorphosed and adult ranids in the terrestrial and aquatic environments, and this technique has potential for many more applications in anurans and other small animals, such as monitoring of animals in the shallow subterranean environment. Limitations for PIT tag and PIT-pack use are tag size and limited detection range. We successfully implanted 12-mm tags into ranids > 30 mm SVL. Currently available, 8-mm tags should be suitable for frogs > ~ 20 mm SVL and ~ 0.7 g, but use with smaller animals is not possible due to tag size. Also, additional work is needed to assess the long-term affects of tagging on animals of this size. A PIT-pack can detect 100% of tags in the terrestrial environment to a depth of 13 cm and > 90% of tags to a depth of 20 cm.

Acknowledgments.—We thank Dawn Bavaro, Rebecca Dionne, Alicia Miller, Valerie Moreau, and Brian Shaw for their help in the field and lab. Frogs were collected under Maine Department of Inland Fisheries and Wildlife Permits 05–281 and 06–377, and experiments were conducted under University of Maine IACUC permit A2006–03–03. This research was supported by the LEAP project (Land-use Effects on Amphibian Populations, National Science Foundation Grant No. 0239915) and the USGS Maine Cooperative Fish and Wildlife Research Unit. Mention of trade names does not imply endorsement by the U.S. government. We thank Aram Calhoun, Daniel Harrison, Cynthia Loftin, and Alan White for improving the manuscript. Biomedical researchers are examining the venoms of several reptiles in their search for bioactive peptides that may be beneficial to human medicine (Chen et al. 2002; Raufman 1996). Acquiring venom for research can be problematic. Some venoms are commercially available from biochemical supply companies, while others, such as Beaded Lizard *(Heloderma horridum)* and Gila Monster *(H. suspectum)* venoms, may only be periodically available (in our experience), may be of suspect origin, and are expensive. Therefore, researchers may have to collect venom from live or recently killed animals they have direct access to. In the past, proteomic and genomic research on helodermatid venom toxins often resulted in animal sacrifice or surgical removal of the lizard's venom glands (Chen and Drucker 1997; Pohl and Wank 1998).

Sacrificing animals for such research may be deemed objectionable on moral and ethical grounds or present conservation concerns. Thus, researchers may need to collect venom from live lizards, but this, too, can be problematic.

Helodermatid lizards are protected, either federally (in Mexico) or by state governments (in the U.S.), and all helodermatids are listed under CITES (Levell 1997). Thus, it can be difficult to acquire these animals. Venom collection from helodermatids may prove difficult due to the nature of the helodermatid venom apparatus (Strimple et al. 1997). Additionally, work with live venomous lizards presents safety risks, both to the researchers and the lizards, and necessitates special training and equipment to manipulate them safely (Poulin and Ivanyi 2003). Surprisingly, helodermatid bites are not uncommon and, at a minimum, these bites can be extremely painful. The only fatalities reported from Gila Monster bites are suspect (Beck 2005; Brown and Carmony 1999), but its venom and that of *H. horridum* can have systemic effects that can be life-threatening to humans, including a rapid drop in blood pressure (which can result in hypotensive shock) (Burnett et al. 1985; Preston 1989), severe angioedema (Piacentine et al. 1986), coagulopathy and renal failure (Preston 1989), acute myocardial infarction (Bou-Abboud and Kardassakis 1988), and anaphylaxis (Cantrell 2003).

We explored several published methods of helodermatid venom collection wherein the investigators forced the lizard to bite the edge of a saucer, which it was inclined to do (and, once the animal had seized the saucer, it was hard to remove); or offering a sponge material for the lizard to bite, with the venom collected from the sponge after the animal released it (Arrington 1930; Mitchell and

FIG. 1. Medicine dropper (60 ml) with rubber bulb, over plastic tube. Note: that only the squeeze bulb with plastic tube is used with this technique.

Reichert 1883; Russell and Bogert 1981). In addition, Stuart et al. (1998) demonstrated the toxic effects that anesthesia and parasympathetic stimulation can have on *Heloderma* while collecting venom. These techniques were found to be impractical, or injurious to the lizards, and/or ineffective. However, modifying the technique of offering a rubber-covered object to bite (Russell and Bogert 1981) worked extremely well.

Materials and Methods.—After the lizard was safely restrained (Poulin and Ivanyi 2003), had opened its mouth and the mouth cavity had been rinsed with water or saline, we presented it with a plastic-reinforced rubber squeeze bulb (14.5 mm diameter) from a Nalgene® 60 ml medicine dropper (Fig. 1). As soon as the bulb contacted the lizard's mouth, the lizard would voluntarily bite down on the bulb. Care was taken to ensure that the posterior teeth (toward the angle of the jaw) engaged the bulb. The lizard was then held with its head at a 30–45° angle (below horizontal) and its mouth was suspended above a glass or plastic vessel (Fig. 2).

Results and Discussion.—After a lizard bites the squeeze bulb, released and compressed its jaws several times, drops of venom would be produced and the venom would drop into the vessel from along the gums of the lower jaw (Fig. 2). Initially, 40 drops (~ 2 ml) of venom were obtained from a several adult specimens. Subsequent trials suggest that this volume of venom can frequently be obtained using this technique but the quantity of venom varies with animal size and vigor (range of 1–4 ml), and it is important to note that the venom may be mixed with saliva and blood. Though the amount of venom per bite diminished after several jaw compressions, generally enough venom was collected in two minutes, allowing us to stop the trial. After each trial, the animal was placed back in its enclosure. In every case, as soon as the lizard was released, it would release the medicine dropper, making it easy to retrieve.

This method was used on six each of *H. horridum* and *H. suspectum* during late morning to early afternoon hours in spring, summer, and autumn. The lizards ranged from subadults (2–3 yrs. old) to large adults (up to 21+ yrs. old), and in both species, males and females were used for venom collection. All of the animals had been in captivity for a minimum of 2 years and a maximum of 21 years. Each lizard would bite and release (but not let go of) the bulb in a rhythmic pattern (i.e., bite and hold down for 4 seconds, bite and hold for 6 seconds, etc.). Though the defensive attitude of animals varied, only the oldest animal (an adult male Gila Monster), displayed less vigor in biting frequency (quantity of bite compressions).

Collected venoms (pooled by species/collection event) were stored at 4°C and immediately transported to a facility for lyophilization and then kept at -80°C. After CITES permits were obtained, lyophilized venoms were shipped to the research laboratory for genomic and proteomic analysis. The lyophilized venoms from *H. suspectum* and *H. horridum* were separately analyzed by gel permeation chromatography, reverse-phase HPLC, and mass spectrometry for the isolation and structural characterization of bioactive peptides. The typical and novel helodermatid venom peptides, exendins and helokinestatin respectively, were both isolated and characterized from the lyophilized venoms collected by this method (Chen et al. 2006; Kwok et al. 2008). The precursor cDNAs of exendin-4 and exendin-3 were also cloned where the lyophilized venoms used as the material for reverse transcriptase PCR (Chen et al. 2006).

Data published by Chen et al. (2006) and Kwok et al. (2008) showed that this technique for helodermatid venom collection worked extremely well. The advantages of this method are that 1) generally it is non-injurious to the lizard; 2) reduces animal stress and the amount of blood from breaking teeth that might be inadvertently collected using other methods (Mitchell and Reichert 1883); and 3) maximizes the quantity of venom that can be safely collected.

The Hellbender (*Cryptobranchus alleganiensis* Daudin) is North America's only member of the Cryptobranchidae, and one of the world's largest salamanders. Hellbenders are elusive animals; they are nocturnal, cryptically-colored, and spend most of their time beneath large rocks on the bottoms of swift-flowing streams. These characteristics make them difficult to locate and capture. A variety of capture methods have been tested and evaluated, but even the most widely accepted of these are still questionable in terms of their impact on breeding habitat and reproductive behavior. In addition, no effective technique has been reported to consistently locate and capture larvae or juveniles.

A common method of searching for Hellbenders involves lifting the upstream ends of rocks greater than 30 cm diameter, and capturing any Hellbender below it by hand or net with or without the aid of a mask and snorkel. Whereas this method is inexpensive and relatively quick (Nickerson and Krysko 2003), turning rocks during the breeding season may disrupt nest sites and result in mortality of eggs or larvae (Williams et al. 1981). Although appropriate for locating large adults, it may be ineffective for locating smaller size classes, especially larvae and juveniles less than 20 cm total length (Peterson et al. 1983). Nickerson and Krysko (2003) speculated that turning small rocks and other objects in shallow water might yield more larval Hellbenders. Additional disadvantages to rock turning include injury to the researcher due to heavy lifting, difficulty seeing Hellbenders because of stream surface glare, possibility of Hellbenders escaping unnoticed by researchers, inability to locate Hellbenders in deep water, and time required for silt to clear after a rock is lifted (Nickerson and Krysko 2003; Pauley et al. 2003).

Electroshocking has been used extensively with high capture success reported (Williams et al. 1981). Bothner and Gottlieb (1991) reported that Hellbenders were completely unaffected by the electrode unless directly touched with it, and even then appeared only mildly disturbed. Regardless of capture success, electroshocking equipment is heavy and expensive, and risk to

researchers and Hellbenders, especially eggs and larvae, is potentially significant (Nickerson et al. 2002; Nickerson and Krysko 2003).

Searching the stream bottom at night using spotlights is another technique that has been used to locate Hellbenders (Humphries and Pauley 2000). Hellbenders observed in the open are captured by hand or net, and rocks are lifted when Hellbender heads are observed protruding out from underneath. Nighttime searches may be useful for determining the presence/absence of Hellbenders during periods of peak nocturnal activity (Humphries and Pauley 2000). Humphries (2007) reported on an apparently unique population in North Carolina that seasonally exhibits a high degree of diurnal activity which made daytime visual searches very productive.

Several attempts have been made to capture Hellbenders using baited traps. Hellbenders are believed to forage at least partially by chemoreception, and have been documented responding to dead bait from a considerable distance (Nickerson and Mays 1973). Wire mesh traps baited with chicken liver proved unsuccessful (Soule and Lindberg 1994), but hoop traps baited with sucker fish did successfully capture Hellbenders (Kern 1984). Despite the mixed success with which traps have been used, they allow researchers to investigate deeper areas, and are not affected by turbidity.

Nickerson et al. (2003) effectively used snorkeling and SCUBA to capture Hellbenders, including larvae, in deep water areas. In their study more than 20 Hellbenders under 20 cm total length were located and 16 of these were gilled larvae. Most were located under small rocks, or in the interstices of small accumulations of gravel or gravel mixed with twigs near the stream banks, but some were located under large rocks in deeper water, or in deep gravel beds. Petokas (pers. comm.) has captured Hellbenders in water as deep as 6 m in the Susquehanna River in Pennsylvania using SCUBA techniques.

The objective of this study was to examine three methods of searching for Hellbenders in terms of efficiency and effectiveness: turning rocks, trapping, and searching along stream banks. Advantages, disadvantages, and limitations also were assessed in order to recommend a capture protocol for Hellbender population studies that will minimize disturbance and increase the likelihood of locating individuals of a variety of size classes.

Materials and Methods

Study Sites

This study was conducted at eight sites in three streams of the Allegheny River drainage in Cattaraugus County, New York, USA. Extant populations of Hellbenders were documented in these sites by a previous study (Bothner and Gottleib 1991). Substrate composition and embeddedness were visually estimated along transects at each site. Percent composition was visually estimated across the entire transect. Embeddedness was estimated at each bank, and at $^1/_4$, $^1/_2$, and $^3/_4$ of the stream width. Three independent estimations were averaged for each transect.

Capture Methods

Rock Turning.—As part of a mark-recapture study, rock turning searches were conducted between late August and October of 2004 and 2005, and generally involved two to four active searchers. Hellbenders were located by slowly lifting the upstream ends of suitable rocks in each study site. A peavey or cant hook was used to provide leverage when needed. Suitable rocks were defined as those measuring at least 30 cm in diameter that did not require the use of multiple leverage devices for lifting. Before lifting a rock, a net was placed against the downstream edge to catch Hellbenders escaping with the silt plume. Hellbenders remaining in place or moving upstream were captured by grasping them behind the head and maneuvering them into a trout net. Rocks deemed likely to be nest sites were not turned in 2005. This is because during the 2004 survey, several nests were discovered and later found to be destroyed, possibly as a result of being disturbed.

Bank Searches.—Bank searches were conducted at all sites during the summer of 2005, between late May and late August, in an effort to locate smaller size classes. This technique was performed by two searchers. Habitable stretches of bank area, defined as having substrate larger than 7 cm in diameter, within the study site were divided into sections 1 m wide and extending 4 m into the stream. Five percent of these sections were randomly selected for search in each site (see Foster 2006 for site descriptions). Searching involved turning or agitating all substrate particles in the section. Aquarium nets with flat bottoms were held downstream to capture any juvenile hellbenders that were observed. Hellbenders were located by feel and captured by hand when visibility was poor.

Trapping.—The traps were a rectangular box design made of 1.3 cm plastic-coated hardware cloth. The traps measured 61 × 46 × 23 cm with a funnel on one end 7.5 cm high and 10 cm wide. A hinged door on the end opposite the funnel, held closed with a bungee cord, could be opened to add bait or remove any captured animals (Fig. 1). During the summer of 2004 we conducted a preliminary trapping test at Site No. 5 to aid in protocol development. We informally tested two baits: previously frozen venison (*Odocoileus virginianus*) and White Sucker (*Catostomus commersonii*). Both baits were selected for their availability, and

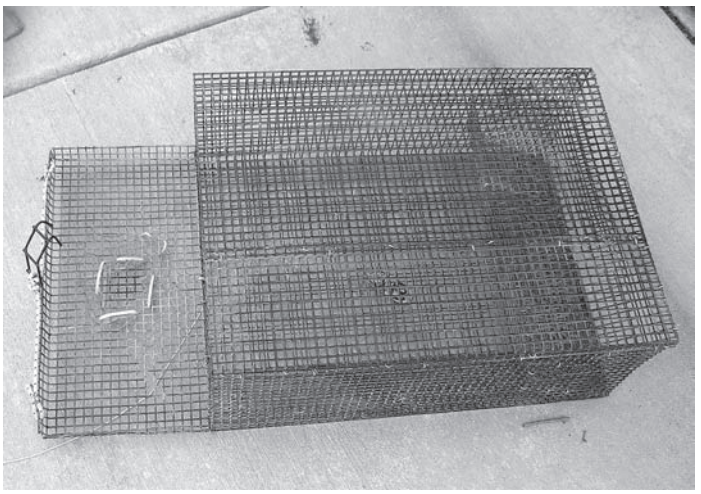

Fig. 1. Trap used to capture Hellbenders in Allegheny River drainage during the summers of 2004 and 2005. Bait (White Sucker) was attached to the inside of the hinged door in a wire mesh cage (later the cage was removed and replaced with plastic zip ties, see text).

sucker fish has been used successfully to capture Hellbenders in hoop traps (Kern 1984). Based on the preliminary data generated, we selected White Sucker as the bait for our future trapping efforts.

Trapping was conducted in all sites during the summer of 2005, between late May and late July. Trapping was performed at one site in May, two sites in June, and five sites in July. We performed four consecutive nights of trapping in each site. The number of traps used varied with site size. Traps were set approximately 20 m apart in potentially habitable areas with sufficient water depth to cover the entire trap (0.25 m minimum). These areas included sections of stream bed covered with large rocks, wood, or decaying vegetation, and areas with rock ledges at the banks. Traps also were set in areas that lacked large cover rocks, but were adjacent to habitable areas. In areas that contained habitat not accessible by turning rocks, such as rock ledges or large, unliftable rocks, and in areas too deep to be searched by hand, traps were set more densely (up to every 5 m). Traps were baited with pieces of White Sucker placed in a wire mesh cage on the trap door (Fig. 1) and set with the entrance facing downstream. In shallow water, traps were set flat against the stream bottom. In deep water, this often was not possible to ensure. Traps were tied to sturdy vegetation and weighted down with rocks. They were checked and bait was changed daily, except for site No. 8, at which bait was only changed every other day. Baiting and setting traps was completed by 1500 h each day, and traps were checked the following morning.

Evaluation of Capture Methods

Efficiency.—Capture efficiency was calculated for each method as the number of Hellbender captures per unit of effort. For the two manual search methods, effort was measured in person hours. Person hours included all time spent actively searching for and processing Hellbenders. Hellbenders were processed as they were found and processing time averaged 8 min/Hellbender. For the trapping method, effort was measured in trap nights. Trap nights were calculated by multiplying the number of traps set by the number of nights deployed. One trap night required 0.5 person hours (it took two people approximately 15 min to bait, set, and check a trap). All Hellbender captures, including recaptures, were included in this analysis.

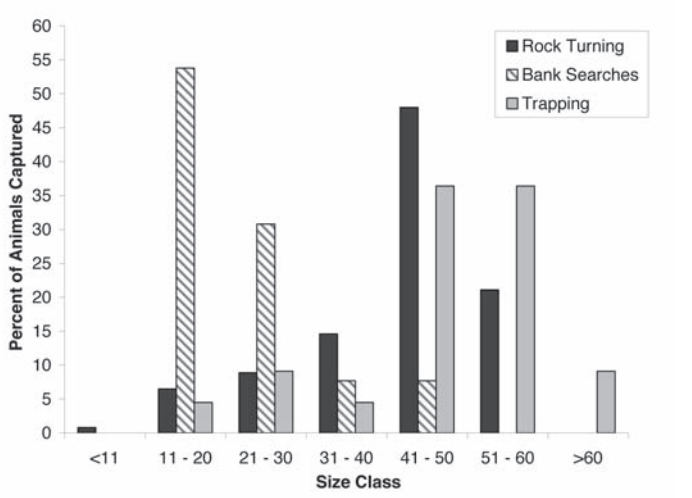

FIG. 2. Relative success of three capture methods in locating various size classes of Hellbenders (Rock Turning, N = 123; Bank Searches, N = 14; Trapping, N = 22; recaptures are not included in these numbers).

Effectiveness.—Each of the three methods was evaluated in terms of its effectiveness at locating Hellbenders of different sizes. Hellbenders were grouped into seven size classes, and the percentage of Hellbenders in each size class was determined for each method. Each animal was only counted once for this analysis, regardless of how many times it was captured. Each technique also was assessed in terms of its ability to capture Hellbenders at different water depths.

RESULTS

Study Sites.—Site areas ranged from 2355 to 15,741 m^2. Substrate in all sites included rocks > 30 cm diameter covering 4–8% of the stream bed, and fine particles (sand and silt) and gravel were prevalent. Site No. 8 also contained large areas of exposed

TABLE 1. Capture efficiency, measured as catch per unit effort, for three methods used to locate Hellbenders in the Allegheny River drainage in New York State. For rock turning and bank searches, effort was measured in person hours. For the trapping method, effort was measured in trap nights. One trap night is roughly equivalent to 0.5 person hours since it takes two people approximately 15 minutes to set a trap. Site No. 3 is excluded because no Hellbenders were observed.

Site	Rock Turning (No. of captures)[1]	Rock Turning (Captures / person hour)	Bank Searches (No. of captures)	Bank Searches (Captures / person hour)	Trapping (No. of captures)	Trapping (Captures / trap night)
1	5	0.21	2	0.50	1	0.03
2	19	0.35	7	0.47	2	0.03
4	33	0.49	0	0.00	4	0.05
5	32	0.55	0	0.00	4	0.03
6	12	0.32	0	0.00	2	0.02
7	33	0.83	5	1.00	1	0.01
8	23	0.64	0	0.00	8	0.10
total	157		14		22	

[1]These numbers include recaptures.

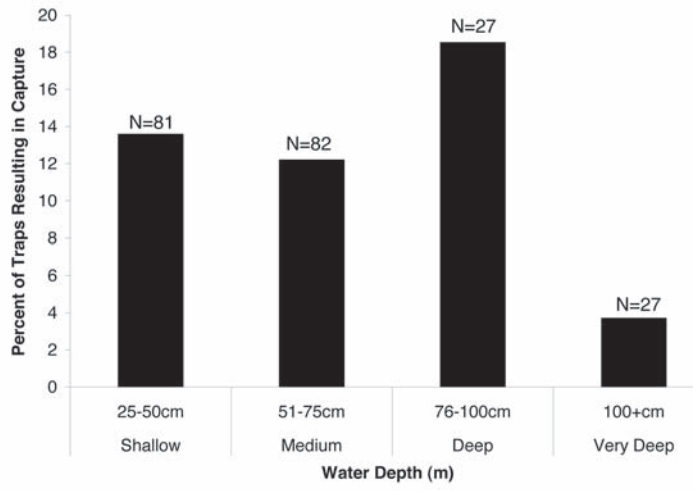

FIG. 3. Relative success of traps placed at different depth ranges. N = number of traps placed at each depth.

bedrock. Substrate embeddedness was greater than 50% at all sites. The study streams were all relatively shallow (< 1 m deep in most places) and very clear during the study period.

Efficiency.—Capture efficiency varied by site for both manual search methods (Table 1). A total of 317 person hours were spent on rock turning and 55 person hours were spent on bank searching. A total of 157 captures (including recaptures) resulted from rock turning searches. Rock turning yielded 0.2 to 0.8 captures/person hour. Bank searches resulted in a total of 14 captures. In four of the seven sites, no Hellbenders were captured using the bank searching method. In the remaining three sites, capture efficiency was higher for bank searching than for rock turning, ranging from 0.47 to 1.0 captures/person hour. Traps were set for a total of 627 trap nights among all seven sites, resulting in 22 captures. Capture efficiency was highly variable between sites, ranging from 0.01 to 0.10 captures/trap night (Table 1). Only rock turning resulted in recaptures.

Effectiveness.—Each of the three methods was successful at locating both adult and juvenile Hellbenders, but only the two manual search methods resulted in the capture of gilled larvae. The smallest animal, less than 11 cm total length, was captured using the rock turning method. Captures of very large Hellbenders, greater than 60 cm total length, resulted only from the use of traps. No method was capable of locating all size classes equally (Fig. 2). Rock turning searches were biased toward middle-sized adults, between 41 and 50 cm total length. Of 123 individual Hellbenders captured using this method, 48% were in this size class. Bank searches were biased toward immature animals. Of the 14 Hellbenders captured in bank searches, 53.8% were between 11 and 20 cm total length. An additional 30.8% were between 21 and 30 cm total length. Trapping was most successful in capturing large adults. More than 80% of the 22 Hellbenders captured in traps were greater than 40 cm total length.

Each method was capable of locating Hellbenders at a range of depths, although manual search methods were limited to water <1 m deep. Bank searches were successful within the narrowest depth range, from 0.145 to 0.540 m. Rock turning captures ranged in depth from 0.155 to 0.85 m. Trapping had the greatest successful depth range, with Hellbenders captured from 0.28 to 1.25 m depth.

TABLE 2. Summary of advantages, disadvantages, and limitations associated with three Hellbender capture methods used in the Allegheny drainage in 2004 and 2005.

Method	Advantages	Disadvantages	Limitations
Rock Turning	- High capture efficiency - Locates some juveniles - Risk of injury to Hellbender - May reduce reproductive success (if done during breeding season)	- Labor intensive - May damage habitat - High turbidity - Low light - Rock size and mobility - Depth - Minimum of five person hours per site recommended	- Wind - Rain
Bank Searches	- Effective for finding juveniles - High capture efficiency where successful - Potential impacts to reproduction of other stream organisms - May fail to detect presence	- Does not result in high capture rate for larvae - Habitat disturbance	- High turbidity - Rock density - High flow
Trapping	- Little habitat disturbance - Useful for water slightly exceeding maximum depth of other methods - Useful for areas with unliftable rocks or ledges - Captures largest size class - Only method that detected Hellbenders at all sites	- Labor intensive - Low capture success - Requires large supply of bait - Risk of injury to Hellbender - Incidental catch may result in mortality of turtles - Cannot use during breeding season - Did not detect larvae	- Shallow water (< 0.25 m deep) - Deep water (> 1 m deep) - Minimum of 100 trap nights / site recommended

Trapping appeared to be most successful in deep water, between 0.76 and 1.0 m (Fig. 3). Of 27 traps set at this depth range, 18.5% resulted in captures. Less than 15% of traps set in shallower areas resulted in captures, and fewer than 4% of traps set in water >1 meter were successful in capturing Hellbenders.

Discussion

Of the three methods examined, rock turning was the most efficient when viewed in terms of overall catch per unit effort. However, in some streams, bank searches were also highly efficient. Capture efficiency for trapping was lower than for rock turning in all sites, and was lowest in terms of overall catch per unit effort.

Bank searches were notable in the "all or nothing" type of capture success seen between sites. At all three sites where the method was successful, it exceeded the capture efficiency of rock turning. In the remaining four sites, it yielded no captures. This disparity is most likely due to differences in habitat between the sites. Bank searches were successful where stream margins included deep cobble piles interspersed with larger rocks. These areas presumably provide refuge from predation and an abundant food supply.

Sites at which bank searches were unsuccessful fell into two categories: those at which bank habitat was poor, and those at which bank habitat was exceptionally good. Poor bank habitat was characterized by silt and sparse rock cover. Exceptionally good bank habitat was characterized by dense piles of various-sized cobble and boulder along the stream edges. These areas were difficult to search thoroughly. It is possible that employing seines, buried into the substrate on either end of the search area, might increase the success of this method in areas with good habitat.

The capture rate for rock turning can be impacted by water and weather conditions. Hellbenders are difficult to see when the surface of the water is choppy. When turbidity is high, Hellbenders are often lost in the silt plume that is generated by lifting the rock. Under certain circumstances, a mask and snorkel might help alleviate these problems (Nickerson and Krysko 2003). Early in our study we tried using a mask and snorkel for both rock turning and bank searches, but because our streams were extremely shallow and clear this method did not prove useful. Even in our streams, SCUBA may have been useful for turning rocks in deep pools. However, we did not attempt this method and thus could not manually search for Hellbenders in areas deeper than ca. 1 m.

The usefulness of trapping may be limited by the nature of Hellbenders as predators. Hellbenders often lie in wait for prey, with only their noses protruding from rocks (Humphries and Pauley 2000), utilizing a powerful type of suction feeding enabled by unique jaw asymmetries and hyoid movements (Lorenz Elwood and Cundall 1994). This may limit their need to move about in search for food (Nickerson and Krysko 2003), reducing the likelihood of their capture using traps. On the other hand, Humphries and Pauley (2000) suggest that during times of high metabolic demand Hellbenders may forage more actively. This may increase trapping success at some times of the year, especially prior to the breeding season.

Prey availability may influence Hellbender foraging. Large numbers of crayfish were observed in our sites throughout the study period, which may have minimized trapping success. Bait choice also may affect trapping success. Although White Sucker was successful in capturing Hellbenders in our study, other baits may prove more enticing. For example, Hellbenders may be attracted to bait with fresh blood (Bishop 1941).

Traps appeared to be most successful when set at depths between 0.75 and 1.0 m. Few Hellbenders were trapped at depths >1 m, possibly due to difficulty in setting traps flat against the stream bottom at these depths. This problem could be corrected by diving to the bottom using a mask and snorkel or SCUBA equipment and properly setting the trap. Diving to set deep-water traps may be useful if rock ledges or unliftable rocks are present.

Each of these methods has associated advantages and disadvantages that affect their usefulness in various situations (Table 2). Rock turning may be the most efficient method for capturing Hellbenders, but may have serious repercussions during the breeding season. Hellbenders tend to select nest rocks that are mostly embedded in smaller substrate and have only a single opening, which the male defends (Bishop 1941). Once the nest is disturbed, several openings may exist, exposing the eggs or larvae to a variety of predators. In addition, overturning potential nest rocks may render them unsuitable as nest sites because they will no longer be sealed by small particles.

Bank searches are extremely useful for locating juvenile Hellbenders, but may be highly disturbing to the habitat. Many organisms may be affected, including crayfish, small fish, mudpuppies, tadpoles, and macroinvertebrates. While not impacting Hellbender reproduction, bank searches during the summer may affect the reproduction of some other organisms.

Trapping was the only method that did not cause substantial disturbance to the stream habitat. It also worked in situations where other methods failed, such as in habitat areas with very large rocks or rock ledges. Of the 22 Hellbenders trapped in 2005, 16 were not located using any other method. Of these, one was trapped near a rock ledge, seven were trapped near unliftable rocks, and five were trapped in deep water.

Trapping also has some disadvantages. Traps are heavy, bulky, and take a considerable amount of time to set. There is risk of injury to Hellbenders. Several Hellbenders sustained minor injuries on the original wire bait holder. As a result we removed the holders and used plastic zip ties to hold bait for the remainder of the study. There is also a risk to other animals that may become caught in the trap, particularly turtles. Trapping should not be conducted during the breeding season, since females captured in traps overnight could become stressed and drop their eggs, and captured males would be prevented from returning to their nests rocks, possibly exposing eggs to predation.

When determining which capture method to use for studying a particular group of Hellbenders, it is important to consider the attributes of the site and the advantages versus the disadvantages of each method. Our results suggest that no single method for Hellbender capture is capable of providing access to all portions of the population. Based on its high catch efficiency and ability to locate some juveniles, rock turning is most likely the best method for studies aimed at determining population size. The inclusion of rocks smaller than 30 cm diameter in bank areas may increase the ability of this method to provide information on age structure. However, the main advantage of rock turning in the breeding season, gathering sex ratio data, is outweighed by the potential negative impacts to reproductive success. To provide the most complete

data on Hellbender population structure, including age structure and habitat usage, we recommend a combined approach using extensive summer rock turning, bank searches focused on appropriate cobble piles adjacent to large rock areas, and limited trapping in areas of deeper water, or where unliftable substrate renders other search methods impossible.

Acknowledgments.—We thank Richard Bothner for advice and helping to find the original sites. We are greatly indebted to the following people for help in the field: Joshua Daigler, Dan Kinsey, Gary Klock, Brian Landahl, Holly Morehouse, Noelle Rayman, Heather Warner, and numerous others we may have unintentionally missed. Thanks to Chris Pennuto for field advice and manuscript review. Thanks also to Chris Phillips and two anonymous reviewers. This project was supported in part by State Wildlife Grant T-2-1 from the U.S. Fish and Wildlife Service to the NYS Department of Environmental Conservation and administered by Buffalo State College. Field work was conducted under a protocol approved August 2, 2004 by Buffalo State College's Institutional Animal Care and Use Committee.

The diverse array of collection methods used to sample freshwater turtles (e.g., Gibbons 1990; Glorioso and Niemiller 2006; Plummer 1979; Vogt 1980) do not necessarily provide equivocal results in ecological studies of freshwater turtles. Using different methods may significantly influence estimates of abundance, sex ratio, and population/community structure (Frazer et al. 1990; Gamble 2006; Ream and Ream 1966; Thomas et al. 1999). Frazer et al. (1990) argued that studies designed to compare different methods of capturing turtles were needed to ensure that the results of ecological studies accurately reflect reality.

Baited funnel traps of various designs are commonly used to sample freshwater turtle populations/communities, using a variety of baits (see Gibbons 1990; Kennett 1992; Plummer 1979). We are aware of three published studies that attempt to quantitatively compare the effectiveness of different baits on the capture rate of freshwater turtles (Ernst 1965; Jensen 1998; Voorhees et al. 1991). We experimentally examined the effectiveness of three types of bait in funnel traps to capture *Trachemys scripta elegans* and *Chrysemys picta bellii*. The baits selected were canned creamed corn (*Zea mays*), canned Jack Mackerel (*Trachurus symmetricus*), and frozen fish (*Pomoxis annularis* or *Lepomis cyanellus*); these baits were selected because they were commonly used in previous studies.

Methods.—Rectangular frame nets (65 × 90 cm frame covered with 3.8 cm treated nylon mesh; Nichols Net & Twine Inc.) were used to capture Red-eared Sliders (*T. s. elegans*) and Western Painted Turtles (*C. p. bellii*) in a complex of eight manmade ponds (pond sizes ranged from 0.2–9.6 ha) located on or within 2.5 km of Emporia State University's Ross Natural History Reservation (RNHR; Spencer 1988) near Americus, Kansas, USA (38.49491°N, 96.33540°W; NADS 1983). Three frame nets were set in each of the eight ponds (total = 24 frame nets). Baits were placed in perforated PVC tubes so that turtles could detect but not consume baits. The three frame nets within each of the eight study ponds were baited either with canned creamed corn, canned jack mackerel, or frozen fish (i.e., each of the three frame nets within a single pond were baited with a different bait). The initial assignment of bait

type to the three frame nets within a pond was random. Thereafter, frame nets were checked daily and the position of the PVC tubes containing the different baits systematically rotated daily among the three frame nets. The purpose of systematically rotating the baits among the three traps within each pond was to equally distribute the possible influence of differences in capture rates between specific trap locations within a given pond. Baits were removed from the perforated PVC tubes and replenished with fresh bait every other day.

Frame nets were set in 1–3 ponds/day over the 5 d period that began 14 May 2007. We reversed this staggered schedule for removal of frame nets at the end of the 13 d study period to maintain an approximately equal number of trap hours in all ponds. Thus, all ponds were sampled continuously for a total of 13 d with substantial temporal overlap of the trapping schedules (i.e., all trapping conducted from mid- to late May). There were 3 traps/pond for 13 d in eight ponds (overall, 7488 trap hours summed across all three baits, 2496 trap hours/ bait, 936 trap hours/pond, and 312 trap hours/pond/bait).

All *C. p. bellii* and *T. s. elegans* captured were uniquely marked using the system described by Cagle (1939). We considered all captures (original captures and recaptures) as independent in statistical analyses.

Trap success may have been influenced by inherent site-specific variation among the eight ponds and/or the temporal variation that may have resulted from slight differences in the precise trapping schedules among sites. Because of possible site-specific variation, we used Analysis of Variance (ANOVA) within a randomized block design to compare the mean number of turtles (of each species) captured with each of the baits during the 13 d study period. Blocking designs are desirable in such situations because they increase the precision of the model by removing one source of known (or suspected) variation (e.g., inherent site-specific variation in capture rates among ponds) from experimental error (Peterson 1985; Sokal and Rohlf 1995). The eight study ponds were considered as blocks, the different baits were the treatments, and mean number of turtles (i.e., either *C. p. bellii* or *T. s. elegans*) captured/pond with each of the three baits served as the response variable. Separation of means was accomplished using Fisher's Protected Least Significant Difference (LSD; Peterson 1985) and alpha was set at 0.05 in all statistical tests.

Results.—We captured 93 (69 original captures + 24 recaptures) *C. p. bellii* and 81 (50 original captures + 31 recaptures) *T. s. elegans* during the 13 d study period. We captured *C. p. bellii* in all ponds and caught *T. s. elegans* with one or more of the baits in all but one pond. Therefore, we excluded this pond from the analyses for *T. s. elegans*. We observed a significant bait effect for both species (*T. s. elegans*: F = 5.25; d.f. = 2, 12; P = 0.023; R^2 = 0.69; *C. p. bellii*: F = 4.73; d.f. = 2, 14; P = 0.027; R^2 = 0.75). We captured significantly more *T. s. elegans* in frame nets baited with frozen fish than with creamed corn, but observed no significant difference between frozen fish and canned mackerel or between canned mackerel and creamed corn (Fig. 1A). Mean separation procedures for *C. p. bellii* revealed that both canned mackerel and frozen fish were significantly more effective than creamed corn but canned mackerel and frozen fish were not significantly different from each other (Fig. 1B).

Discussion.—We concluded that both canned mackerel and frozen fish were significantly "better" than creamed corn for attracting these two species to frame nets. First, we discuss several potentially confounding factors that are known to influence capture rates. For example, captured females may serve as an additional enticement for males to enter nets (Frazer et al. 1990; Jensen 1998; Thomas et al. 1999). However, we did not observe unusually large numbers of males within traps containing females (see Jensen 1998), and we see no reason to expect that the particular food bait within a trap would alter the attractiveness of a female within that trap. Therefore, the influence of this factor should have been equal across all three baits. Likewise, individual turtles sometimes exhibit so-called "trap-happy" or "trap-shy" behaviors (Deforce et al. 2004; Koper and Brooks 1998). But, we do not think that the observed differences were an artifact of such behaviors. First, because of the short duration of our study period many individuals were never recaptured (i.e., captured only once) and most of those that were recaptured were recaptured only once. Second, turtles were not rewarded for entering a trap (i.e., not allowed to consume the baits) and the bait tubes were systematically rotated every day among the three traps within each pond. Therefore, we have no reason to expect the propensity for "trap-happiness" or "trap-shyness" to have differed among the three baits. Therefore, the influence of such behaviors (if any) should have been equal across all three baits.

Consistent with previous studies, we found that using different

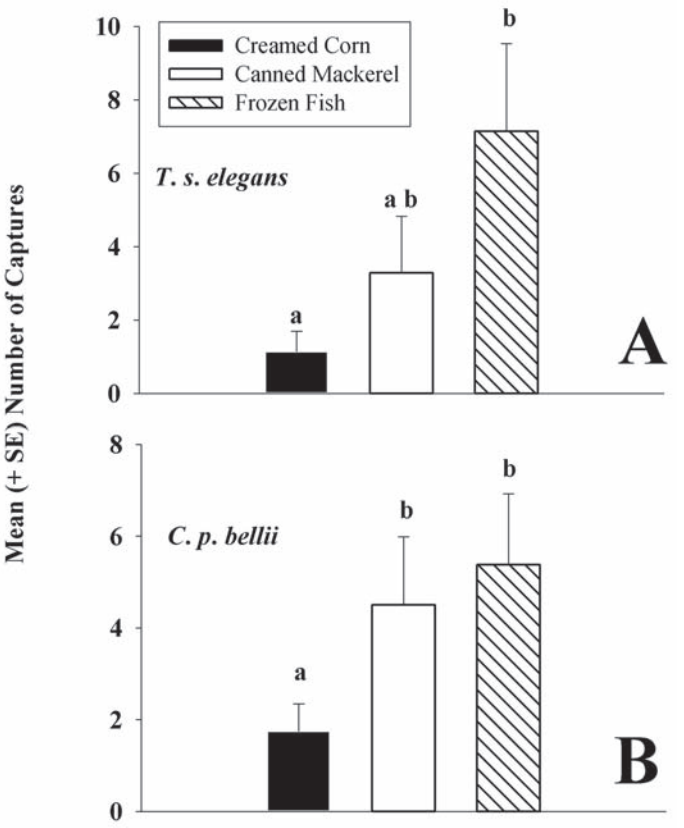

FIG. 1. Mean (+ SE) number of turtles captured/pond during 13 days of trapping (A = *Trachemys scripta elegans*; N = 7 ponds; B = *Chrysemys picta bellii*; N = 8 ponds) with canned creamed corn, canned mackerel, and frozen fish. Means sharing the same lower case letter were not significantly different (Fisher's Protected LSD; α = 0.05).

baits sometimes resulted in differences in capture rates. But various factors limit our ability to directly compare our results with those of previous studies. For example, the three published studies (Ernst 1965; Jensen 1998; Voorhees et al. 1991) were conducted in different geographic locations and/or habitats, sometimes used different baits, and/or involved different species. Our study was conducted in manmade ponds located within a small portion of east-central Kansas and we cannot necessarily assume that our results are applicable across the relatively large geographic distributions of these species. We examined three commonly used baits but there are a large number of baits that have been used as bait in funnel traps. Currently, nothing is known with respect to the relative effectiveness of most of these baits. Likewise, the potential for seasonal, sexual, and ontogenetic variation in the effectiveness of particular baits deserves further consideration.

Acknowledgments.—We thank landowners P. F. DeBauge, P. Matile, R. Moore, and A. S. Webb for generously granting permission to trap in their ponds. We acknowledge the support of the Emporia State University Department of Biological Sciences and thank the department for allowing access to ponds located on the RNHR. We thank T. Gamble for reviewing a previous version of the manuscript. This study was partially funded by an Emporia State University (ESU) Faculty Research and Creativity Grant to R. B. Thomas and an ESU Graduate Student Research Grant to I. M. Nall. All applicable Emporia State University animal care and use policies were followed during the study. Turtles were collected under permit number SC-127-2006 issued to R. B. Thomas by the Kansas Department of Wildlife and Parks.

A Simple Pitfall Trap for Sampling Nesting Diamondback Terrapins

The Diamondback Terrapin *(Malaclemys terrapin)* is an estuarine turtle inhabiting coastal salt marshes from Massachusetts to Texas (Ernst et. al. 1994). Previous data on nesting terrapins have primarily been collected via visual searches during peak nesting activity (Feinberg and Burke 2003; Roosenberg 1996; Roosenberg and Dunham 1997). Although effective, this method is time consuming, requires a reasonably large population, and sometimes requires numerous volunteers. Many of these studies occurred along the Atlantic Coast where nesting beaches are located on the mainland. This has allowed researches to easily access nesting beaches to conduct visual searches for terrapins. Nesting beaches in the Northern Gulf of Mexico, however, are located almost exclusively on islands (D. H. Nelson, pers. comm.), making nesting beaches accessible only by boat. Boat travel results in increased travel time and thus decreased searching time for nesting terrapins. To complicate matters, nesting beaches in the northern Gulf Coast are usually small and widely distributed, making typical nesting surveys almost impossible to conduct (Nelson et. al. 2005). Unlike Atlantic coast nesting beaches, beaches in Alabama are largely composed of oyster shells, which prevents locating turtles and their nests via female crawls (a method used in Feinberg and Burke 2003). Given these atypical nesting conditions, we decided that a passive trapping method would be more appropriate for capturing terrapins on local nesting beaches.

Initial efforts with pitfall traps constructed from Christiansen and Vandewalle (2000) fell short of our expectations. These traps did not hold up to the demands of the estuarine environment (e.g., saltwater, winds). Specifically, the wooden lid and metal rod degraded quickly, rendering the trap non-functional. Furthermore, 5-gallon buckets did not seem to provide suitable space for trapped terrapins to maneuver. We used the Christiansen and Vandewalle (2000) design as a starting point and began experimenting with various modifications of their design. Herein, we describe the

modified design that best addressed the specific problems described above.

We erected four, 90-m long drift fences on shell middens (composed of oyster shell) at Barton Island (30°23'N, 88°22'W), Mon Luis Island (30°20'N,88°11'W), and Cedar Point (30°19'N, 88°08'W) in southern Mobile County, Alabama, USA. Pre-staked construction silt fencing, 90 cm in height, was used for several reasons including, low cost, ease of handling, and durability. Fences were buried to a depth of 30 cm leaving 60 cm above ground. Two pitfall traps were installed along each fence 30 m from the ends and 30 m apart. Pitfalls had a self-righting lid that was placed over the pitfall (Fig. 1). This type of lid was chosen for two reasons: 1) to increase the numbers of turtles that were captured, since turtles seemed wary of uncovered pitfalls (Christiansen and Vandewalle, 2000), and 2) to provide shelter from thermal stress. Temperature was monitored in the month of June (tropical storms prevented sampling temperature in July) using HBE International Inc. Minimum-Maximum thermometers. One thermometer was secured with cable-ties midway inside a pitfall trap, while another thermometer was staked on exposed shell adjacent (outside) to the same pitfall trap. Thermometers were reset everyday to acquire daily temperature extremes. Minimum temperature inside the pitfall ranged from 18°C to 23°C and a maximum temperature ranged from 25°C to 29°C. Temperatures outside the pitfall had a minimum range of 24°C to 30°C and a maximum range from 40°C to 47°C (N = 20 days).

Each trap consisted of a single 68.1 L (19 gal) plastic storage container. The rigid construction of the Sterilite® brand worked better than other available styles, as shifting sand and shells of nesting beaches tended to warp and distort other plastic containers. To prevent water accumulation from rain and/or over wash caused by storm events, holes were drilled through the bottom of the containers. The lid was designed to rotate when a large or heavy animal walked across one side or the other. The lid returned to its original, horizontal position after a turtle fell into the trap via a pendulum. Construction of the rotating lid assembly began by drilling holes in the handles where 15.2 cm (6 inch) steel I-bolts were mounted on each handle with 3/8 inch washers and nuts to create a mount for the rotating lid. Next, the outer edges of the lids were cut to fit inside the container, which allowed the lids to rotate freely inside the pitfall trap. The lid was very flimsy, so 1/2 inch PVC tubing was used as a framework for the rotating lid and attached to the lid with 20.4 cm (8 inch) cable ties. The PVC was cut to fit through the I-bolts and capped to prevent sliding of the lid assembly. A hole was cut at the center of the lid for a pendulum to pass through into the pitfall. The pendulum consisted of a 15.2 cm (6 inch) section of 1/2 inch PVC, filled with lead fishing weights, attached to the central rib at the T-joint. The pendulum allowed the rotating lid to remain level even during high winds and right itself after a turtle was captured.

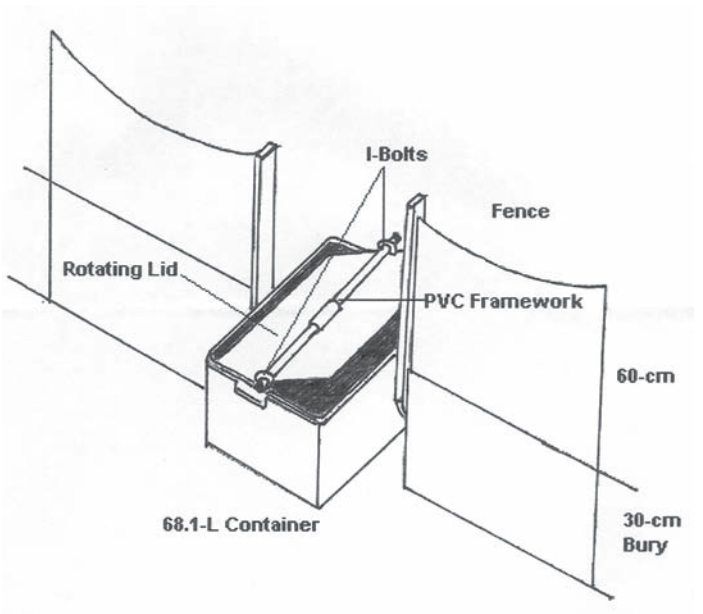

FIG. 1. Diagram for 68.1 L (19 gal) pitfall trap with self-righting lid, shown attached to a drift fence. (Illustration provided by B. Gill)

The labor and construction cost involved in erecting the fences and burying the pitfalls was minimal compared to hourly monitoring of nesting beaches. Total cost of one 90 m fence with two pitfall assemblies was US $90, and each array required 2 person-hours for construction and instillation. No part of the traps needed to be replaced throughout the nesting season, which included two tropical storm events.

From 13 May to 19 August 2005, we successfully captured 14 gravid female terrapins 16 times in 310 trap days (one trap day = one pitfall open for one night) for a catch per unit effort of 0.05 terrapins per trap day. Capture rates were greater than those of modified crab traps (similar traps used by Wood 1997) sampled near the nesting beaches, 21 captures over 2048 trap days (0.01; Borden, unpubl. data). Although catch per unit effort was low, terrapin populations in Alabama appear to be uncommon to rare and highly isolated (Nelson and Marion 2004). During the nesting season, the plastic pitfalls did not degrade. However, it was necessary from time to time to adjust the fit of the lid with a utility knife to ensure unobstructed rotation. We opened traps on Mondays and closed them on Fridays. Traps were checked daily. When not in use, we covered traps with a 60 × 80 cm piece of rubber-coated chicken wire and staked the wire at each corner, to prevent the inadvertent capture of terrapins. We observed no apparent predation on terrapins within the traps, although Raccoons *(Procyon lotor)* and River Otters *(Lontra canadensis)* were observed on the nesting beaches. Although nesting beaches are used by humans, there was no evidence of trap disturbance during this study.

We found this technique to work well for terrapins inhabiting estuaries with minimal nesting habitat. However, it may be less effective than visual searches in habitats with expansive or readily accessible nesting beaches. Longer drift fences with more pitfalls will need to be tested to determine their effectiveness at large nesting areas. Possible disadvantages of this technique are that nesting females may be forced to alter nesting behavior when they encounter the fence. In our experience, however, turtles nested along and even beneath drift fences with no adverse impacts.

In conclusion, although pitfall traps have been used to capture turtles for many years (Congdon et. al. 1987; Gibbons et. al. 1983; Tucker 2000), our trap is the first to incorporate a pendulum and the first designed for harsh, estuarine environments. This trapping system will be appreciated by terrapin researchers along the northern Gulf Coast where typical capture methods (e.g., visual transects, locating signs of nesting females) are not effective. Overall, this

trapping system seems to be a relatively inexpensive and time saving technique for sampling terrapins in an undersampled portion of their range.

Acknowledgments.—We thank D. Nelson for sharing his knowledge of Diamondback Terrapin nesting habitat in Alabama. We also thank the University of South Alabama Biology Department for logistical support. We thank B. Jones, B. Gill, and A. Coleman for their assistance with construction of the drift fence and pitfalls. We are grateful to the Grand Bay National Estuarine Research Reserve staff and Grand Bay US Fish and Wildlife Refuge Manager P. Dixon who provided detailed site descriptions, maps, and aerial photography. Funding for this project was provided by the Alabama Center for Estuarine Studies through a grant to D. Nelson. The University of South Alabama Institutional Animal Care and Use Committee approved animal care guidelines. Terrapins were captured with permission of the Alabama Department of Conservation and Natural Resources.

Genetic analysis has been applied extensively to studies of wildlife populations to examine population diversity, gene flow, inbreeding depression, source-sink dynamics, and extinction-recolonization frequencies (Hedrick and Kalinowski 2000; Jehle and Arntzen 2002). Blood or tissue samples and buccal swabs are the common source of DNA for most genetic studies. In chelonians, blood samples are acquired by drawing blood from the tail, leg, or neck (Avery and Vitt 1984; Jacobson et al. 1992; Rosskopf 1982). Although effective, obtaining blood samples is invasive, sometimes difficult to accomplish, and possibly stressful to the turtle. However, alternative methods have also had serious drawbacks, including a protocol using shell samples that required such large amounts of bone that either a deceased animal was needed or the animal had to be sacrificed (Hsieh et al. 2006).

In this paper, we describe a method of obtaining tissue for genetic studies that makes use of the traditional marking techniques for turtles, i.e., drilling or notching the marginal scutes (Cagle 1939; Ernst et al. 1974; Mockford et al. 1999). The drill shavings produced during marking are used as the source of DNA for genetic analysis instead of being thrown away thereby eliminating the invasive and stressful procedure of blood extraction and increasing the speed with which the samples can be taken.

Materials and Methods.—All samples collected came from gopher tortoises at the Kennedy Space Center (Brevard and Volusia Counties, Florida, USA) where mark-recapture studies have been conducted for over 30 years (Pike et al. 2005). Tortoises collected were examined for previous marks and mass and length measurements were recorded (Pike et al. 2005). While wearing sterile gloves, 100% ethanol was used to swab the scute area to be drilled in order minimize contamination of the sample. A 1/8th inch (3.17 mm) drill bit was used to drill holes in scutes of unmarked tortoises, while a larger bit was used to drill holes in scutes of previously marked individuals. Filter paper was placed under the scute area where the hole was drilled to catch the drill shavings during the marking process. Drill shavings from one or two holes were enough to facilitate genomic DNA extraction. After drilling, the shavings were placed in a sterile 15 ml polypropylene tube, and stored at ambient temperature. After a tortoise was marked, the drill bit was cleaned by brushing with a firm toothbrush dipped in 100% ethanol. The drill bit was then dipped in 100% ethanol and flamed to sterilize. (Note: Isopropyl alcohol could be substituted for ethanol.)

The extraction process used two 5/8th inch (15.88 mm) hex bolts

and a matching nut. Prior to use, the threaded end of the bolts were ground flat to provide an even grinding surface to maximize the pulverization of the drill shavings (Thomas and Moore 1997). The nuts and bolts were then wrapped in aluminum foil and sterilized in an autoclave. The nut was partially threaded on to one bolt creating a small cup that was then filled with approximately 0.1 g of drill shavings. The second bolt was added to make a sealed chamber encapsulating the drill shavings (Thomas and Moore 1997). The bolt assembly was placed in liquid nitrogen for 30 seconds to one minute (Thomas and Moore 1997). Upon removal from the liquid nitrogen, the sample was pulverized by simultaneously twisting both bolts together. The bolt assembly was tightened and loosened several times and tapped on the hard surface to assure the sample was uniformly pulverized (Thomas and Moore 1997). The bolt assembly was then carefully dismantled over a piece of filter paper to collect the powder and facilitate transfer to a 1.5 ml microcentrifuge tube.

The powdered drill shavings were decalcified in 500 µl of 0.5 M pH 8.0 EDTA at 37ºC while shaking at 225 rpm until the pellets had broken down, (approximately three to five days) following a modified protocol for the Qiagen DNeasy Blood and Tissue kit (Qiagen, Valencia, California) (Qiagen 2006). The decalcification step is critical since the cells containing DNA must be freed from the calcified matrix in order for the extraction to be successful. The samples were centrifuged at 13,000 rpm to pellet and washed three times with sterile deionized water to remove ions that had accumulated during the decalcification process. Decalcified samples were then processed using a Qiagen DNeasy Blood and Tissue kit following the modified protocol above.

Results.—A total of 0.1 g of drill shavings yielded enough DNA for multiple genetic analyses. Total DNA yields ranged from 110 to 4650 ng. The high molecular weight DNA produced with this method has been verified by ultraviolet spectrophotometry and PCR. Ratios of A260/A280 measurements ranged from 1.6 to 2.0. PCR amplifications with seven species-specific microsatellite primers produced strong, clear bands in >91% of the samples tested.

Discussion.—Our results show that DNA can be obtained from a standard method of marking turtles. By refining and combining existing techniques, we have developed a protocol that requires lesser amounts of shell material and minimizes the invasive procedures when compared to currently published techniques. The drilling or filing of the marginal scutes has been observed to show no signs of physical pain in the animals (Gibbons 1968). Pike et al. (2005) also noted that handling and drilling stress wore off quickly enough to have no discernable effect on recapture rates, demonstrating that drill marking has little detrimental effect on tortoises. Mockford et al. (1999) described a similar protocol for DNA extraction from freshwater turtle hatchlings; however it is important to note that the shell material was not ossified at the time of removal making the DNA extraction process less problematic.

Our technique provides the basis to easily gather and process genetic material from ossified shell to examine chelonian genetic diversity and long-term viability. A better understanding of the population structure and effective populations of these long-lived and slow reproducing animals is necessary to properly formulate management strategies for these animals (Gibbons et al. 2000; Scott and Seigel 1992). Our protocol uses a waste product of a common marking technique to obtain high-quality DNA allowing for the addition of genetic analysis to ongoing mark-recapture studies. Our technique enables non-invasive sampling of a population to get DNA samples of comparable quality to those obtained with more invasive methods.

Acknowledgments.—Special thanks go to R. Bolt for her constant and gracious help with this project. Much of what we have done could not have been accomplished without her assistance. Thanks also go to S. Weiss and P. Cain for their help in locating tortoises for this study. We would also like to thank T. Crabill for her advice on bucket trap placement and J. Sinclair for his valuable comments on this manuscript. We are also grateful to R. Hinkle of Dynamac and J. Stiner of the National Park Service for financial support. We thank personnel from the Merritt Island National Wildlife Refuge (especially M. Epstein and M. Legare) for providing permits to conduct this study. We also thank the Canaveral National Seashore (J. Stiner) for logistical support and special use permits. All procedures were approved by the NASA Animal Care and Use Permit #GRD-06-042 with R. Bolt as the point of contact.

Amphibian chytridiomycosis, a disease caused by the fungus *Batrachochytrium dendrobatidis* (*Bd*), has been documented in numerous wild populations in North America (Ouellet et al. 2005), including an Illinois population of Blanchard's Cricket Frog (*Acris crepitans blanchardi*) (Pessier et al. 1999). Herein we document the possible occurrence of *Bd* in this species in Ohio in 1999 and the likely occurrence of *Bd* in populations from Missouri in 2001 and Michigan in 2004.

On 16 September 1999, 10 Blanchard's Cricket Frogs were collected at St. Mary's Fish Hatchery in Auglaize County, Ohio, and transferred to the Toledo Zoo where they spent 10 days in isolation before being sent to the Detroit Zoo, Michigan. By 20 September 2000, eight frogs had been moved from their quarantine enclosure to a native-Michigan, mixed-species amphibian exhibit. The other two frogs were missing from their quarantine enclosure and presumed dead; it is not unusual for small amphibians to decompose completely before their death has been detected, particularly in naturalistic enclosures. The first two confirmed deaths were over a year after their arrival in Detroit and within months of their addition to the mixed exhibit (10 December 2000, 7 February 2001); these two frogs tested positive histologically for *Bd*. As the *Bd* treatment protocol had only recently been published (Nichols and Lamirande 2000) and was not yet known by zoo staff, nothing was done for the animals remaining in the exhibit. Three more frogs died between 27 February 2001 and 10 July 2003: histopathology results were inconclusive for two, and *Bd* was not detected histologically in the third. Two additional frogs were missing and presumed dead at that time also. On 30 March 2003, an American Toad (*Anaxyrus americanus*) in that exhibit died; this animal tested positive histologically for *Bd*. Medication with the established protocol (Nichols and Lamirande 2000) was begun for the other amphibians in that enclosure in late July 2003. The last cricket frog died on 22 July 2003 while under treatment for *Bd*; there was no histologic evidence of active *Bd* infection, but there was mild multifocal epidermal hyperplasia likely from previous *Bd* infection. There are two scenarios that could explain the presence of *Bd* in this group of cricket frogs from Ohio. The wild population could be infected and these frogs could have entered the collection asymptomatically carrying *Bd* and gradually succumbed over nearly four years. Although some species susceptible to *Bd* tend to die within a few weeks of infection, others can carry light infections of the disease with no clinical symptoms and only succumb under duress. In this case, the last cricket frog survived over two and half years after the first *Bd*-positive death in the enclosure. The other possibility is that, since the two positive cases were not detected until after the group was moved into the mixed-species exhibit, the cricket frogs could have been infected by the other amphibians in that exhibit, which could have been asymptomatic. Two of the three other taxa (*Anaxyrus americanus*, *Notophthalmus viridescens*, but not *Lithobates pipiens*) eventually tested positive.

On 22 October 2001, 10 Blanchard's Cricket Frogs were collected from Franklin County, Missouri, and transferred to the Detroit Zoo. All were dead within four months. Four frogs died in quarantine throughout December 2001; histopathology results were inconclusive. The remaining six frogs were moved on 2 January 2002 into a general holding room with other species but were maintained in isolation in their own enclosure. Two more frogs were dead by 10 January 2002; histopathology results on these frogs were also inconclusive. The seventh frog died on 29 January 2002; this frog tested positive histologically for *Bd*. The remaining three frogs were dead by 18 February 2002 before we learned the results from the seventh frog and had a chance to medicate them using the established protocol; histopathology results were inconclusive. The *Bd* in these animals could have come from poor husbandry (transmission from other isolated asymptomatic animals), but because these frogs were in an isolated enclosure with dedicated tools during their entire time in captivity, more likely they came infected from the wild.

From 4 August through 7 October 2004, 835 Blanchard's Cricket Frog adults and 176 tadpoles were collected from a wetland in Ypsilanti, Washtenaw County, Michigan, where their native habitat was slated for development. These frogs were held temporarily in isolated quarantine at the Detroit Zoo, then released into three newly constructed local wetland sites from 24 August to 7 October 2004 (Rickard et al. 2004). Histopathology results from three frogs and four tadpoles collected and sacrificed a month prior to translocation revealed no *Bd* or other diseases. While they were in captivity, 181 frogs died. Of those, eight were submitted for histopathology and the last two tested positive for *Bd*. Because these animals were kept in isolated quarantine in a new building with no other amphibians, it is likely that they came infected from the wild.

In all three cases, there is a possibility that the *Bd* in the captive cricket frogs originated from other animals in the captive collection. However, we feel that this is rather unlikely, at least in the two cases where the animals were kept isolated from others in the collection. In the future, we recommend testing for *Bd* in all amphibians arriving into captive collections. Not only will this benefit the health of the captive collection, it can also provide valuable data on the distribution of *Bd* in the wild. *Bd* is not something most zoos test for in quarantine, although a simple PCR test is now available (Annis et al. 2004) and might someday be afford-

able for such routine testing. Sampling a subset of the animals is cheaper, but as in the case of the cricket frogs from Michigan, it can lead to oversight.

Batrachochytrium dendrobatidis is a chytrid fungal pathogen of amphibians that has been implicated in a number of amphibian declines (Berger et al. 1998; Lips et al. 2006). However, despite the importance of *B. dendrobatidis* as a potential causative agent of population declines and biodiversity loss in amphibians, many questions remain regarding this pathogen and its impact. Most importantly, we still have relatively few data on which species are infected by *B. dendrobatidis*, if infection is commonly associated with declines, and the geographic scope of its occurrence. Even in North America, where the amphibian fauna is relatively well-known, only a small number of studies have examined infection and distribution patterns of *B. dendrobatidis*.

Blanchard's Cricket Frog (*Acris crepitans blanchardi)* is a small North American hylid that was formerly one of the most common frogs in North America (Gray et al. 2005). Recently, serious declines have been reported in Blanchard's Cricket Frog populations throughout much of the midwestern United States, particularly the northern and western parts of its range (Brodman and Kilmurry 1998; Hay 1998; Lannoo et al. 1994; Lehtinen 2002; Lehtinen and Skinner 2006; Mierzwa 1998; Mossman et al. 1998). A number of hypotheses have been proposed to account for the asymmetric decline of Blanchard's Cricket Frog including: habitat loss and fragmentation, drought and climate change, contaminants, competition and/or predation by fish or other amphibians, and changes in local and regional successional patterns (Beasley et al. 2005; Gray and Brown 2005; Hammerson and Livo 1999; Hay 1998; Irwin 2005; Jung 1993; Lannoo 1998; Lehtinen 2002; Lehtinen and Skinner 2006; Reeder et al. 2005; Russell et al. 2002). The potential involvement of *B. dendrobatidis* in the decline of this species is clearly another hypothesis in need of investigation. Here we report on tests for the presence of *B. dendrobatidis* in Blanchard's Cricket Frog.

Methods.—Skin swabs or tissue samples from 205 Blanchard's Cricket Frogs were collected from 21 haphazardly chosen ponds in six states in the midwestern United States (Fig. 1). Most samples (N = 197) were collected between June and October of 2006 from live frogs in the field. A small number of samples (N = 8) came from venter skin sections of alcohol-preserved museum specimens collected in April 2002 and June 2003. Most samples were from juveniles or adults but a small number of larvae were also sampled. Skin swabs were obtained by running a sterile cotton swab along the skin of the captured frog for approximately 30 seconds, focusing on the hands, feet and pelvic region. For larvae, swabbing was concentrated around the oral apparatus. Tissue samples were either toe clips or skin sections. Toe clips were removed from live frogs using sharp, sterilized scissors. Both skin swabs and tissue samples were preserved in 70% ethanol in 2.0 ml screw-capped microcentrifuge tubes. In a few cases, voucher specimens were retained for reference purposes (deposited at the Illinois Natural History Survey and the James Ford Bell Museum of Natural History), otherwise frogs were released at the site of capture. All

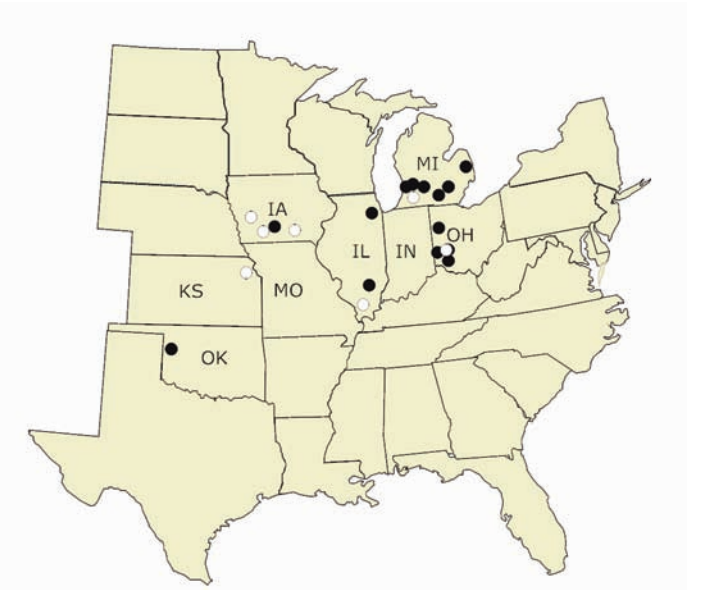

Fig. 1. Geographic distribution of sites where Blanchard's Cricket Frogs were sampled in the U.S. Midwest. Filled dots indicate sites where *B. dendrobatidis* was detected with the PCR assay. U.S. States: IL = Illiniois; IN = Indiana; IA = Iowa; KS = Kansas; MI = Michigan; MO = Missouri; OH = Ohio; OK = Oklahoma.

TABLE 1. Prevalence of *B. dendrobatidis* infection of Blanchard's Cricket Frog (*Acris crepitans blanchardi*) samples from the midwestern U.S., as determined by standard PCR assay.

State	County	Locality	Latitude	Longitude	No. infected / total sampled	Prevalence of infection
Ohio	Auglaize	St. Marys Fish Hatchery	40.526°N	84.418°W	6 / 42	0.14

Oklahoma	Ellis	Packsaddle Wildlife Area	35.846°N	99.616°W	1 / 9	0.11

samples were transported to the College of Wooster (Wooster, Ohio) for processing with a PCR-based assay.

All DNA from tissue samples were extracted according to the animal tissues protocol provided by the manufacturer (Qiagen, Valencia, CA; DNeasy Blood and Tissue Handbook, 07/2006). Skin swab samples were agitated for thirty seconds in a vortex and the swab was removed and squeezed along the side of the tube to remove the maximum amount of solution. An aliquot of 300 µl was removed from the tube and centrifuged in a 2.5 ml tube for five minutes. The supernatant was subsequently removed and the remaining pellet was used for the remainder of the extraction procedure. Following the extraction procedure, all samples were concentrated to approximately 20 µl by centrifugal evaporation.

Amplification of the extracted samples was completed with standard polymerase chain reactions (PCR) using the primers reported in Annis et al. (2004). Amplification reactions consisted of 13 µl of deionized water, 5.0 µl of template (containing approximately 10–30 µg of DNA), 2.5 µl 10x PCR buffer (Qiagen, Valencia, CA), 2.5 µl dNTPs (10 uM of each), 1.0 mM $MgCl_2$, 0.5 µl of each primer at a concentration of 50 pmol/µl, and 0.25 µl *Taq* polymerase (5 units/mL) in a volume of 24 µl. The amplification of the mixture took place according to the following steps: an initial denaturation at 94°C for 10 minutes, followed by 30 cycles of 45 seconds at 93°C and 45 seconds at 60°C, and then a final extension at 72°C for 10 minutes to complete the amplification. Products were then viewed on ethidium bromide stained 1.0% agarose gel dissolved in TAE (40 mM Tris [pH 8.0], 20 mM acetic acid, 1 mM EDTA) alongside a 1 kb ladder. A band approximately 300 base-pairs in length indicated the presence of *B. dendrobatidis* infection.

A positive control of *B. dendrobatidis* broth culture and zoospores was used to optimize and determine the sensitivity of the PCR assay. A dilution series of the positive control was run and successful amplification took place in 1/5, 1/10, 1/50, 1/100, and 1/500 dilutions. All PCRs were run twice for each sample. Amplification in both replicates was considered a true positive signal of infection, while no amplification in both replicates was considered a true negative signal. Templates that amplified once were subject to a third replicate, in which a successful amplification was taken as indicating infection. To avoid false-positive and false-negative results, negative and positive controls were used with all samples analyzed.

Available information suggests that declines in Blanchard's cricket frogs may be moving from north to south, and inward from both the western and eastern range boundaries (Lannoo and Grundel 2004; Lehtinen and Skinner 2006). Based on where declines have been reported, we used chi-squared analyses to test for differences in infection prevalence north and south of three latitudes (38°N, 40°N, and 42°N) and east and west of two longitudes (88°W and 90°W). Also, the difference in prevalence of infection between skin swab samples and tissue samples was tested using a chi-square test. All statistical analyses were performed using SPSS (version 13.0, SPSS Inc., Chicago).

Results.—*Batrachochytrium dendrobatidis* was detected in 15.1% (31 of 205) of samples from Blanchard's Cricket Frogs (Table 1). Within infected sites, prevalence of infection was generally low (18.8 ± 9.8%; Table 1). We did not detect *B. dendrobatidis* at seven sites but all of these localities had relatively small sample sizes. In all sites where more than ten frogs were sampled, *B. dendrobatidis* was detected (Table 1). No dead, dying or obviously diseased frogs were found at any of the investigated sites.

Infected frogs were found in Ohio, Michigan, Iowa, Illinois, and Oklahoma (but not in any of the five samples from Kansas; Table 1). There was no obvious geographic pattern in infection. Infection rates did not differ significantly at longitudes greater and less than 90°W or 88°W ($\chi^2 = 1.281$, df = 1, P = 0.258; $\chi^2 = 1.130$, df = 1, P = 0.288, respectively). Prevalence of infection also did not differ significantly at latitudes greater and less than 38° N ($\chi^2 = 1.407$, df = 1, P = 0.236), 40°N ($\chi^2 = 0.784$, df = 1, P = 0.376), or 42°N ($\chi^2 = 0.136$, df = 1, P = 0.712). The prevalence of infection did not differ significantly between samples obtained by skin swabbing and those from tissue samples ($\chi^2 = .273$, df = 1, P = .0602).

Discussion.—We document the widespread presence of *B. dendrobatidis* in populations of Blanchard's Cricket Frogs in the midwestern United States. Although *B. dendrobatidis* is now known from captive situations (Zippel and Tabaka 2008), to our knowledge, this is the first documented case of *B. dendrobatidis* infection in cricket frogs from wild populations. However, no mortality was found or reported in these infected, yet seemingly healthy cricket frogs. Additionally, we have mark-recapture data from one of these populations since 2004 (St. Marys Fish Hatchery, Ohio; R. Lehtinen, unpubl. data). This population has maintained a large and relatively stable population size over the last four years (2004–2007), despite *B. dendrobatidis* infection. In this respect, our results parallel Ouellet et al. (2005) who found *B. dendrobatidis* to be enzootic in Quebec with no symptoms associated with infection. It is possible that Blanchard's Cricket Frogs utilize antimicrobial skin peptides (Woodhams et al. 2006) or behavioral thermoregulation (Woodhams et al. 2003) as defenses against *B. dendrobatidis*, but these possibilities have yet to be investigated. While preliminary, our data suggest that Blanchard's Cricket Frog populations are able to persist in the face of ongoing *B. dendrobatidis* infection (e.g., Daszak et al. 2005; Retallick et al. 2004).

We found *B. dendrobatidis* to have no obvious geographic pattern of occurrence. In fact, *B. dendrobatidis* was present at every site where ten or more samples were available. These data reinforce the observations of others that *B. dendrobatidis* appears to be widespread in North America (Longcore et al. 2007; Ouellet et al. 2005; Pearl et al. 2007). Importantly, we detected *B. dendrobatidis* both in areas where Blanchard's Cricket Frog declines have occurred (Ohio, Michigan, northern Illinois) as well as where declines have not been reported (Oklahoma, southern Illinois). The apparent absence of declines in more southerly parts of the range suggests that *B. dendrobatidis* may not be solely responsible for recent population declines in Blanchard's Cricket Frogs further north. However, more northerly populations could be more vulnerable to infection since *B. dendrobatidis* grows best in cooler temperatures (Longcore et al. 1999) and the amphibian immune system functions most effectively at higher temperatures (Maniero and Carey 1997). The declines in the northern portions of the range could also have resulted from earlier declines caused by *B. dendrobatidis* that have now stabilized. Similar patterns of persistence with *B. dendrobatidis* after initial declines are known (Retallick et al. 2004; Woodhams and Alford 2005). More work is clearly needed to assess what threat (if any) *B. dendrobatidis* infection poses to Blanchard's Cricket Frogs.

Many records of *B. dendrobatidis* infection in North American anurans are from ranid and bufonid frogs (e.g., Ouellet et al. 2005; Pearl et al. 2007). Fewer hylid species have been reported to be infected. Using histological techniques, Ouellet et al. (2005) reported *B. dendrobatidis* infection in *Pseudacris triseriata* (54 out of 143 individuals) and *Hyla versicolor* (1 out of 16). However, Longcore et al. (2007) found no infection in *Hyla versicolor* (0 out of 50), or *Pseudacris crucifer* (0 out of 21). Pearl et al. (2007) also found no infections in *Pseudacris regilla* (0 out of 28) in the Pacific Northwest. Our results with *Acris crepitans* (31 out of 205) suggest that *B. dendrobatidis* may be more widely distributed in North American hylids than previously suspected.

Acknowledgments.—We thank Dean Fraga for help with laboratory procedures and Nate Busman for help in the field. Janalee Caldwell, Jeff Davis, Tony Gamble, Karen Kinkead, Chris Phillips, and Edi Sonntag collected and sent us cricket frog skin swabs or tissue samples from their respective study areas and they have our sincere thanks for making these available. We thank Corinne Richards for supplying the zoospores for the positive control and the protocols for the skin swab DNA extraction procedure. We thank the Henry J. Copeland Fund and the Biology Department at the College of Wooster for funding this project which was a senior Independent Study project by the lead author. The Institutional Animal Care and Use Committee at the College of Wooster approved the methods used in this project. Cricket frogs were captured in Ohio under permit 06-266 from the Ohio Division of Wildlife and in Michigan under a scientific collector's permit from the Michigan Department of Natural Resources.

The emerging infectious disease chytridiomycosis has been implicated in the decline and extinction of numerous amphibian species worldwide (Berger et al. 1998; Lips et al. 2006; Skerratt et al. 2007). The fungus causing this disease, *Batrachochytrium dendrobatidis* (*Bd*), has been present in North American amphibian populations since at least the 1960s (Ouellet et al. 2005); however, in many areas of North America, there is little evidence of negative effects of the disease on amphibian population persistence. Understanding how environmental factors affect infection prevalence is thus important for determining under what conditions chytridiomycosis is likely to have a devastating impact on populations.

We conducted a preliminary assessment of the role of season and habitat quality on chytridiomycosis infection prevalence in populations of the Wood Frog, *Rana sylvatica*, in southeastern Michigan, USA. In laboratory studies, *Bd* appears to be limited by temperatures outside the range of 4–25°C (Piotrowski et al. 2004). Several studies also have noted that the prevalence and severity of infections in wild populations tend to vary seasonally (Berger et al. 2004; Kriger and Hero 2006, 2007; Retallick et al. 2004; Woodhams and Alford 2005). Given this, we predicted that levels of infection would be higher in the spring as opposed to the summer because the warmer temperatures experienced during the summer months in southeastern Michigan should limit *Bd* infection rates (Berger et al. 2004; Kriger and Hero 2006, 2007; Ouellet et al. 2005; Retallick et al. 2004; Woodhams and Alford 2005; Woodhams et al. 2003). Additionally, habitat quality may affect

infection rates because the higher stress levels associated with low quality habitats may make individuals more susceptible to infection (Carey and Bryant 1995). Ponds that are exposed to high levels of agricultural and urban runoff may be particularly stressful for amphibians. For example, both pesticides (Relyea 2005) and road de-icing salt (Sanzo and Hecnar 2006) affect larval Wood Frog survivorship. Thus, we predicted that Wood Frog (*Rana sylvatica*) populations in ponds surrounded by agricultural or urban areas would show higher levels of infection than populations surrounded by intact, forested habitat.

Methods.—To assess whether season affects infection prevalence, breeding adults and metamorphs were tested for the presence of *Bd* DNA, since breeding adults often experience colder temperatures than metamorphs. Adults were sampled from eight populations in March 2007 and metamorphs were sampled from five populations in June 2007. All adults and metamorphs were sampled from populations on the University of Michigan's Edwin S. George Reserve (Fig. 1). Temperatures during the 30 days prior to sampling ranged from -16–23°C (mean temperature = 2°C) for the adults and 5–33°C (mean temperature = 20°C) for the metamorphs. The dorsum, venter, and feet of adults and metamorphs were swabbed with a sterile cotton swab. Swabs were stored in 95% ethanol until extraction.

In addition, to assess the relationship between habitat quality and *Bd* distribution, we collected larvae of *R. sylvatica* from 16 populations across southeastern Michigan (Fig. 1) during June 2005 and 2006. Aerial images (Michigan Department of Natural Resources 1998) were used to select ponds with varying degrees of surrounding forest and wetland fragmentation. Larvae were stored in 95% ethanol until extraction. The oral discs of six individuals from each population were excised in the lab using sterilized razor blades and forceps.

Extraction of *Bd* DNA was completed following the methodology of Hyatt et al. (2007). DNA from larval samples was extracted from the oral discs, whereas DNA from the metamorphs and adults was extracted from the swabs. DNA extracted from larvae was pooled in groups of three for each population. The pooled-larval samples and both the adult and metamorph samples were then diluted 1:10 with double deionized water. Taqman diagnostic quantitative PCR (Boyle et al. 2004) was used to detect the presence of *Bd* DNA. Quantitative Taqman PCR assays were performed in triplicate using an Applied Biosystems Prism 7700 Sequence Detection System following the protocol of Boyle et al. (2004). VIC$_{TM}$ Exogenous Internal Positive Control reagents were used for the detection of PCR inhibitors (Applied Biosystems following Hyatt et al. 2007). Inhibitors did not appear to be present in any of the samples. A sample was only considered positive for *Bd* if all three replicates indicated the presence of the fungus. Samples testing positive in one or two replicates were re-assayed once. If the second assay produced a consistent negative or positive result for all three replicates the sample was considered negative or positive, respectively. Samples testing positive in one or two replicates of the second assay were considered "suspicious." Prevalence rates were calculated by dividing the number of infected individuals by the total number of sampled individuals, and 95% confidence intervals were calculated based on a binomial distribution (Stata Intercooled v. 10.0).

The percentage of combined agricultural and urban land cover within 1 km (estimated genetic neighborhood size of *R. sylvatica*: Berven and Grudzien 1990) of each of the 16 ponds sampled for larvae was calculated in ArcGIS v. 9.2 using the 2001 National Land-Cover Database (Homer et al. 2004). This percentage ranged from 6.18 to 78.55 (Table 1).

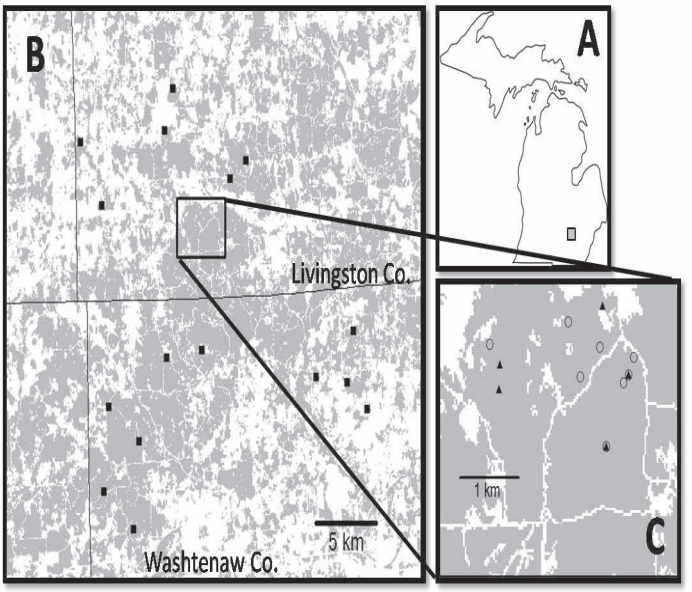

FIG. 1. Wood Frog (*Rana sylvatica*) sampling locations in southeastern Michigan, USA, showing areas sampled for *Batrachochytrium dendrobatidis* in adults (open circles), metamorphs (triangles), and larvae (squares). Agricultural and urban areas are white. Forests, wetlands, rivers, and lakes are gray.

Results.—Two of 239 (prevalence = 0.83%; 95% confidence interval = 0.1–3.0%) samples tested positive for the presence of *Bd*. One of 70 (1.4%) adults, zero of 73 metamorphs, and 1–3 of 96 (1.0–3.1%) larvae tested positive in each of three replicates. The range surrounding the number of infected larvae arises from pooling the larvae into groups of three for the analyses. As a result, a positive sample indicates that at least one of the three individuals was positive for *Bd*. In addition, one of 70 (1.4%) adults tested positive in two out of three replicates and thus was classified as suspicious.

Discussion.—We found a very low level of *Bd* infection in populations of *R. sylvatica* in southeastern Michigan (0.83%). Other studies of North American *R. sylvatica* populations have found much higher rates of infection (15.5%, Longcore et al. 2007; 6.6%, Ouellet et al. 2005). We calculated 95% confidence intervals for each of these studies to assess the extent to which our results differed from these previous studies and found that our confidence intervals did not overlap (Longcore et al. 2007: 6.4–29.4%; Ouellet et al. 2005: 3.4–11.1%). Our results are consistent with the idea that the quality of the habitat and the season may be important predictors of infection rates. For the effects of season, we found one adult that tested positive for *Bd*, while no metamorphs tested positive. Temperatures during the adult breeding period remained at or below the optimal temperature range for *Bd*, whereas during the metamorph sampling period, temperatures exceeded the maximum temperature at which *Bd* can survive in the laboratory (Piotrowski et al. 2004). Similarly, we detected *Bd* in larvae in a pond exposed to one of the largest areas of anthropogenic distur-

TABLE 1. Wood Frog (*Rana sylvatica*) larval infection rates in relation to amount of agricultural and urban habitat surrounding ponds in southeastern Michigan, USA.

Percent Agricultural/ Urban Land Cover	Number Infected/ Sample Size
6.18	0/6

65.39	(1–3)/6
78.55	0/6

bance in this study (Table 1). However, the low level of infection we found prevents us from testing our hypotheses statistically. Future research on the effects of habitat quality and seasonality on *Bd* infection prevalence remains a priority.

Two hypotheses may explain the low infection levels detected in this study, given the high prevalence of *Bd* both worldwide and in other areas of the Wood Frog's range. First, the more terrestrial life-history of *R. sylvatica* may help prevent infection in this species (Longcore et al. 2007). *Rana sylvatica* is an explosive breeder that breeds in early spring. Larvae develop and metamorphose in approximately 6 weeks, and juveniles then move into the terrestrial habitat for foraging (Regosin et al. 2003). In comparison to other co-occurring species, wood frogs are in the ponds for a shorter amount of time. These results are consistent with Lips et al. (2003) hypothesis that the probability of decline as a result of *Bd* infection is positively related to the amount of time the species spends in aquatic habitats. However, while rates of infection in *R. sylvatica* are typically lower than in other co-occurring species (Longcore et al. 2007; Ouellet et al. 2005), the levels of infection in *R. sylvatica* seen in this study are much lower than in other studies, suggesting that other factors may have contributed to the low prevalence of *Bd* across southeastern Michigan.

Second, it is possible that habitat differences between southeastern Michigan and other parts of *R. sylvatica*'s range could account for the low infection prevalence seen in our study, as compared with other studies. Differences in climate, for instance, in temperature or the amount of rainfall, are associated with differences in infection rates (Kriger and Hero 2007), and thus may dictate the range over which *Bd* is viable. However, this seems unlikely, because projections from an ecological niche model (Ron 2005) suggest that the habitat of southeastern Michigan is more climatically suitable for *Bd* than other areas where *Bd* prevalence in wood frogs has been found to be higher (Longcore et al. 2007). Similarly, differences in the structure of the landscape separating populations may contribute to the variation in infection prevalence across *R. sylvatica*'s range. A fragmented landscape, resulting in reduced connectivity among amphibian populations, may hinder the spread of *Bd* and thus keep regional infection rates low. Further research at a broader geographic scale will be necessary for evaluating whether such habitat differences contribute to the observed patterns of infection in *R. sylvatica*.

Acknowledgments.—We thank Jess Middlemis Maher, Jeff Yeo, and Wendy Luo for their assistance in collecting the data, as well as Deanna Olson and an anonymous reviewer for providing useful comments that helped improve the manuscript. In conducting this research, we have complied with all applicable institutional Animal Care guidelines and obtained all required permits. This research was funded by the University of Michigan's Helen Olsen Brower Scholarship to AJZ.

Amphibian decline is a global phenomenon with multiple causes (Stuart et al. 2004). Some declines have been attributed to the disease chytridiomycosis that affects the skin of amphibians (Skerratt et al. 2007). The agent responsible for chytridiomycosis is the fungus *Batrachochytrium dendrobatidis* (Berger et al. 1998). There is evidence that the spread of *B. dendrobatidis* around the world occurred in the last half century (Ouellet et al. 2005), and there is a need for detailed information on its current spatial extent. In Europe, *B. dendrobatidis* has been reported in several amphibian species in multiple countries, such as Spain, Portugal, Italy, Switzerland, France, Germany and the UK (Cunningham et al. 2005; Garner et al. 2005, 2006; Mutschmann et al. 2000; Simoncelli et al. 2005; Stagni et al. 2004). No comprehensive surveys have occurred in Denmark but a single record of *B. dendrobatidis* for *Rana* kl. *esculenta* on the island of Bornholm is reported (www.spatialepidemiology.net) and confirmed by Trent Garner (pers. comm. to R. Scalera, 2007). Here, we report the results of surveys carried out at four sites in Denmark (Fig. 1) on two native amphibians: *Rana temporaria* and *Rana* kl. *esculenta*.

In summer 2007, we hand captured individual amphibians and sampled them for *B. dendrobatidis* by rubbing a cotton-tipped swab over the body of each individual. Frogs were held separately prior to swabbing and technicians wore a new pair of gloves for each individual handled. The sampling is harmless and was carried out *in-situ* so as to release the sampled animals within just a few minutes at the location where they were captured. As the frog was restrained, the swab was firmly rubbed back and forth 25–30 times, targeting the drink patch, the mouth, and the webbing between each toe. The swab was immediately inserted, cotton side down, into a 2 ml screw-cap tube containing 1 ml of 70% ethanol and stored upright. Vials were shipped to the laboratory for analysis, and each swab was analyzed individually for the presence of *B. dendrobatidis*. Swabs were qualitatively analyzed using a PCR assay (45 amplification cycles). Presence of *B. dendrobatidis* was determined by presence of PCR product visualized on agarose gels (30–90 minute electrophoresis) containing positive controls. Fragments were sized using a molecular weight marker (Pisces Molecular LLC, Boulder, Colorado, USA (Annis et al. 2004; J. Wood, pers. comm.). All field gear was cleaned with a brush and water and then sterilized using a dilute bleach solution between each sampling location.

Two of the 13 amphibians we swabbed were positive for *B. dendrobatidis* (Table 1). We found *B. dendrobatidis* on individuals from both species and at 2 of the 4 study areas we examined. One of the positive results was for an adult of *Rana* kl. *esculenta* captured in Vestamager. The other positive result was for a juvenile of *Rana temporaria* captured in Egense. We did not find any frogs that were dead or that appeared to be sick.

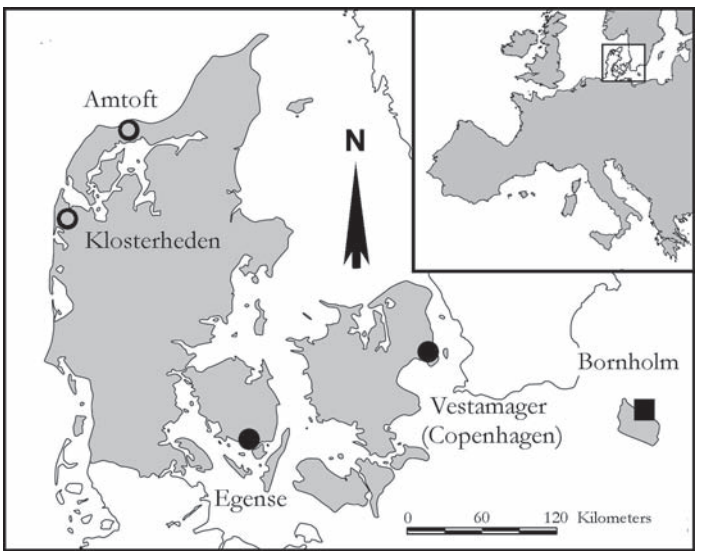

FIG. 1. Locations of study areas in Denmark where amphibians were sampled for the presence of *Batrachochytrium dendrobatidis* in 2007. Circles are filled at locations where we found *B. dendrobatidis*. The square symbol indicates the location of the positive record reported by Trent Garner (see text). Vestamager is located on the island of Zealand, close to Copenhagen, Egense is on Fyn Island, and both Amtoft and Klosterheden are on the Jutland Peninsula.

TABLE 1. Anurans that tested positive or negative for the presence of *Batrachochytrium dendrobatidis* in Denmark in 2007. See Fig. 1 for the locations of the study areas referenced in the table. The species examined were *Rana* kl. *esculenta* (RANESC), and *Rana temporaria* (RANTEM).

Study Area	Latitude	Longitude	Species	Stage	Sex	No. Positive	No. Negative
Egense	55.044167	10.519444	RANTEM	adult	unknown	1	3
Amtoft	57.007500	8.939722	RANTEM	adult	male	0	1
Klosterheden	56.485278	8.362500	RANTEM	juvenile	unknown	0	1
Vestamager	55.614722	12.577222	RANESC	adult	male	0	3
Vestamager	55.614722	12.577222	RANESC	adult	female	0	1
Vestamager	55.614722	12.577222	RANESC	juvenile	unknown	1	2

Further surveys should be undertaken to determine the extent of the pathogen in Denmark. In the meantime, proper sanitizing of equipment would be prudent for anyone entering amphibian habitats. Particular care should be used around sensitive species such as *Bombina bombina*, which is actively managed in Denmark (Pihl et al. 2001), however the threat posed by *B. dendrobatidis* to this and other Danish species is currently unknown.

Acknowledgments.—These surveys were authorized by The Danish Forest and Nature Agency of the Ministry of the Environment with letter of 15 January 2008 (SNS-441-00088). No chemicals or other substances were used on the body of the amphibians and all criteria for the human care of captured animals were followed. Use of trade names does not constitute endorsement.

Amphibian chytridiomycosis, caused by the chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*), has been implicated in the decline and extinction of many populations worldwide (Berger et al. 1998; Lips et al. 2006; Skerratt et al. 2007), and has led to massive die-offs in Latin America over the past few decades (Lips et al. 2006). However, not all populations that carry *Bd* have experienced such declines (e.g., American Bullfrog: Garner et al. 2006; African Clawed Frog: Weldon et al. 2004). Some species have been shown to have physiological (Woodhams et al. 2007a), behavioral (C.L. Richards, pers. comm.), or bacterial (Woodhams et al. 2007b) defenses that may allow them to cope with *Bd*. For many species that have not experienced declines, it is unknown

whether they have lower susceptibility, due to such defenses, or if they have not been exposed to the disease. Evaluation of these alternatives is necessary for distinguishing between species that may be at risk of population declines and those that may be *Bd* carriers.

Despite the fact that an epidemic wave of *Bd* has apparently swept through Costa Rica and western Panama since the late 1980s (Lips et al. 2006), populations of the Strawberry Dart Frog, *Oophaga pumilio*, remain relatively stable. *Oophaga pumilio* is a dendrobatid frog found in rainforests of the Caribbean coast from Nicaragua to Panama. They are found across a range of elevations, from sea level to about 1000 m (Walls 1994). Populations of *O. pumilio* in the Bocas del Toro archipelago in Panama remain abundant and apparently healthy, and we are unaware of any chytrid-related die-offs in other areas of their range or any studies that have assessed *Bd* prevalence in this species. The stability of the Bocas del Toro populations suggests that either *O. pumilio* is able to physiologically or behaviorally cope with the disease or else *Bd* is not present in this region. To distinguish between these alternative hypotheses, we tested for the presence of *Bd* in *O. pumilio* across Bastimentos Island in the Bocas del Toro archipelago, Panama.

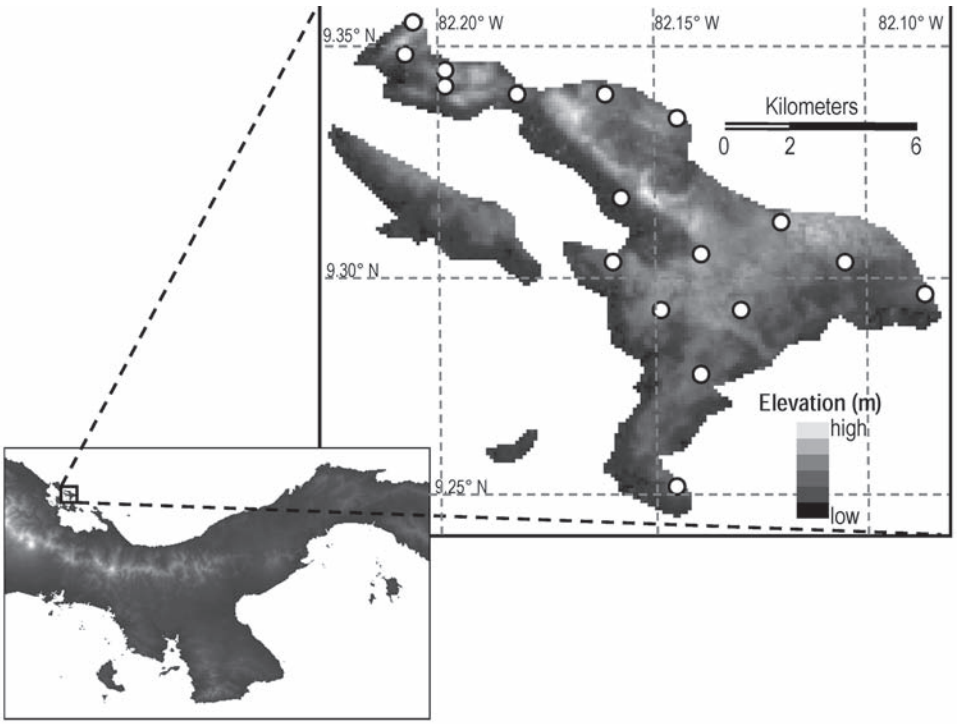

Fig. 1. Sampling locations for *Batrochochytrium dendrobatidis* in *Oophaga pumilio* frogs across Bastimentos Island, Panama.

Methods.—We captured adults from the leaf-litter at 17 transect points across Bastimentos Island (Fig. 1) during July 2007. Sampling locations were chosen to ensure all areas of the island (approximately every 2 km) were assessed for the presence of *Bd*. The dorsum, venter, and feet of five adults from each location were swabbed with a sterile cotton swab for a total of 85 individuals. Swabs were stored in dry microcentrifuge tubes and upon returning to the lab were refrigerated at 4°C until extraction. Individuals were released at the site of capture.

Extraction of *Bd* DNA was accomplished using the methodology of Hyatt et al. (2007). Taqman diagnostic quantitative PCR (Boyle et al. 2004) was used to detect presence of *Bd* DNA. Quantitative Taqman PCR assays were performed in triplicate using an Applied Biosystems Prism 7700 Sequence Detection System following the protocol of Boyle et al. (2004). VIC_{TM} Exogenous Internal Positive Control reagents were used for the detection of PCR inhibitors (Applied Biosystems following Hyatt et al. 2007). A sample was only considered positive for *Bd* if all three replicates indicated a presence of the fungus. Prevalence rates were calculated by dividing the number of infected individuals by the total number of sampled individuals, and 95% confidence intervals were calculated based on a binomial distribution (Stata Intercooled v. 10.0).

Results and Discussion.—None of the 85 individuals sampled tested positive for the presence of *Bd* in any of the three replicates (95% confidence interval = 0–4.2%). Inhibitors did not appear to be present in any of the samples. Our results suggest that there is either a very low level of *Bd* prevalence or that *Bd* is absent from the Island of Bastimentos. We have two hypotheses as to why *Bd* was not detected in our study. First, *Bd* may not yet have reached Bastimentos Island. The geographic isolation of Bastimentos *O. pumilio* populations from mainland populations may have impeded the spread of the disease. The island is, however, heavily traveled by tourists, implying that populations on these islands may be more connected to mainland populations than expected by geography alone.

Alternatively, the apparent absence of *Bd* on Bastimentos could be due to unsuitable environmental conditions. *Bd* is limited by temperatures outside the range of 4–25°C under laboratory conditions (Piotrowski et al. 2004), and the distribution and severity of infections appear to be correlated with rainfall and temperature patterns in wild populations (Kriger et al. 2007). However, *Bd* has been detected in at least one population of Panamanian frogs that

TABLE 1. Climate data for Bastimentos Island, Panama (Hijmans et al. 2005).

Climate Variable	Value
Annual Mean Temperature	25.8°C
Maximum Temperature of the Warmest Month (April)	30.0°C
Minimum Temperature of the Coldest Month (February)	21.0°C
Annual Temperature Range	9.0°C
Annual Precipitation	3109 mm
Precipitation of the Wettest Month (July)	398 mm
Precipitation of the Driest Month (March)	146 mm

is, on average, exposed to slightly hotter conditions than are *O. pumilio* populations on Bastimentos Island (C. L. Richards, pers. comm.). In addition, the average temperature and precipitation on Bastimentos Island (Hijmans et al. 2005; Table 1) is within the range of values for a number of infected sites in Central America (Ron 2005). It is therefore predicted that if *Bd* was introduced to these populations that it would be able to survive.

Identification of areas where *Bd* is absent is crucial for determining the physiological limits of the pathogen and for establishing areas of priority for conservation. Further research on the distribution of *Bd* will provide necessary information for predicting the patterns of spread, potentially assisting managers in preventing outbreaks of the disease.

Acknowledgments.—We thank the staff at the Smithsonian Tropical Research Institute (STRI) for their help with logistics and obtaining permits as well as Deanna Olson and Eli Greenbaum for providing useful comments that helped improve the manuscript. In conducting this research, we have complied with all applicable institutional Animal Care guidelines and obtained all required permits. This research was funded in part by a STRI Short Term Fellowship to CLR.

The amphibian chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*) has been detected in amphibian populations along the northwest coast of North America from Vancouver Island, British Columbia (Adams et al. 2008) north to the Kenai Peninsula (Reeves and Green 2006). However, *Bd* has not been detected in interior Alaska in the Innoko or Tetlin National Wildlife Refuges (Reeves 2008). The Wood Frog (*Rana sylvatica*) is the only amphibian species that occurs in interior Alaska (Wright and Wright 1995) and is susceptible to *Bd* infection (Reeves and Green 2006; Ouellet et al. 2005). In 2006, we sought to determine if *Bd* occurred in Wood Frogs in Denali National Park.

Methods.—Denali National Park (DNP) is located in central Alaska, approximately 183 km S of Fairbanks and 317 km N of Anchorage in Denali Borough (63.97°N, 149.13°W), and covers 2.4 million ha (Fig. 1). Three areas were surveyed for Wood Frogs within the park boundary: Wonder Lake vicinity roadside and backcountry, Teklanika River vicinity roadside, and along the roadside between the park entrance and the Savage River.

Known Wood Frog pond sites were surveyed in the Wonder Lake area (Hokit and Brown 2006), and seven additional ponds with no Wood Frog survey history were selected along the roadside in the Teklanika River vicinity and between the park entrance and the Savage River for their high traffic location. Surveys took place during a two-week period in August 2006 using standard techniques (Olson et al. 1997). Non-invasive techniques were used to

recover skin cells (Boyle et al. 2004; Retallick et al. 2006); each frog was stroked 20 to 30 times on the abdomen, pelvic patch, inner thighs and in between toes or, in the case of larvae, the oral disk was rubbed 5 times in a circular motion with a sterile cotton swab. The swab was then placed individually in a 1.5 ml microfuge tube containing a DNA extraction buffer (Zolan and Pukkila 1986) and stored at ambient temperature. All samples were processed twice by JEJ using polymerase chain reaction (PCR) assay to detect *Bd* (Boyle et al. 2004; Annis et al. 2004). Individual animals were handled with clean latex gloves or a plastic bag inverted over the observers hand. Equipment was sprayed with a concentrated sodium hypochlorite solution between each site. Malformed metamorphs were collected, preserved in a 95% ethanol solution at ambient temperature and x-rayed by a veterinarian to determine if malformations were due to injury or amputation (Summit Industries, Innovet Classic, Model LX125V).

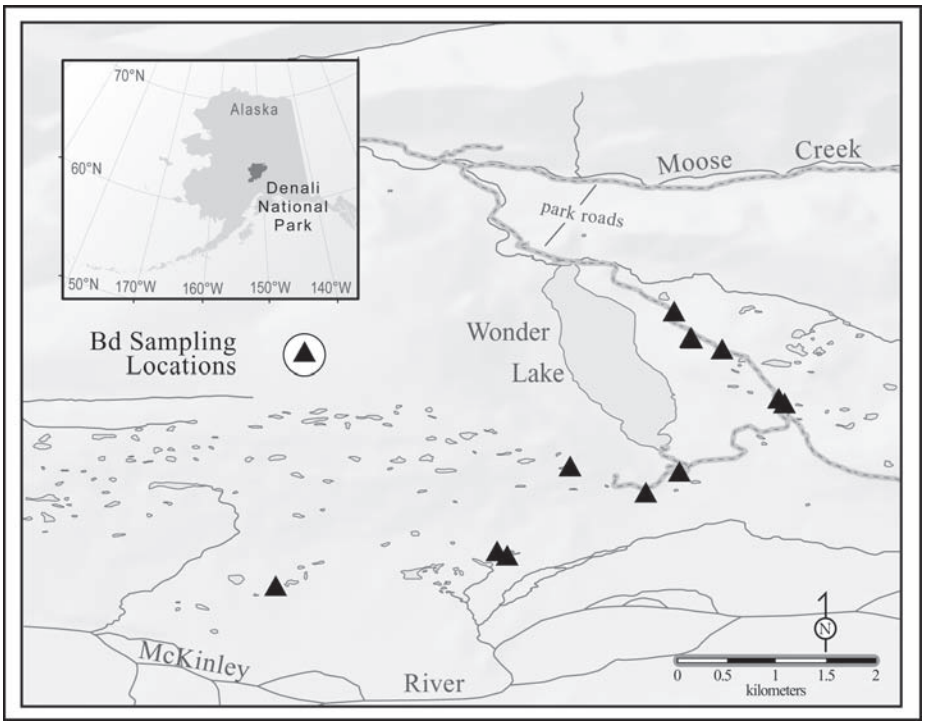

FIG. 1. Denali National Park (DNP), Alaska, USA, and Wood Frog (*Rana sylvatica*) *Bd* sampling locations in the Wonder Lake vicinity.

Results.—We found Wood Frogs at 20 of 26 known sites near Wonder Lake (Fig. 1). Frogs were not found at additional sites searched between the Park entrance and the Savage River or in the Teklanika vicinity, although they were not previously known to be present and may not occur at these sites. Thirty frogs were swabbed, 12 at roadside sites and 18 at backcountry sites up to 4.5 km from the road (Table 1). No *Bd* was detected. Nearly 87% of the animals sampled were newly metamorphosed. At one backcountry site, five (16%) metamorphs were malformed and had missing limbs, and three

TABLE 1. *Bd* was not detected in 30 wood frogs (*Rana sylvatica*) at Denali National Park, Alaska, USA, in 2006.

15 Aug 06	N63 27.646	W 150 53.402	2	Metamorph	Normal	No

(10%) were dead but not obviously malformed. The mechanism of malformation or death is unknown and could not be determined from the x-rays. In addition, one adult frog recovered from a site more than 4 km NNW of the metamorph malformation site was missing a hind limb.

Discussion.—The lack of *Bd* detection does not demonstrate absence from DNP. The low sample size at each site, between 1 and 7 animals, greatly reduces the probability and confidence level of *Bd* detection at each site. *Bd* prevalence varies with a number of abiotic (Berger et al. 2004; Drew et al. 2006) and biotic (Carey et al. 2003) factors. The effect of season (Berger et al. 2004), altitude (Young et al. 2001; Collins et al. 2003), rainfall (Collins et al. 2003), and temperature (Collins et al. 2003) are implicated in *Bd* outbreaks. Amphibians also exhibit differential sensitivity to *Bd* infection depending on life stage (Blaustein et al. 2005; Garcia et al. 2006). *Bd* may be less detectable in newly metamorphosed frogs (J. E. Johnson, unpublished), and may not be reliably detected in some species until two to three weeks after metamorphosis (C. Carey, pers. comm.). Pearl et al. (2007) reported a comparable sample size of juvenile frogs (N = 29) and detected *Bd* in 34.5% of their samples. However, they report fewer *Bd* detections in the summer months (6.15%) compared to the winter months (38.6%) which suggests sampling during the breeding season may improve the likelihood of *Bd* detection. An assay of a greater sample size of Wood Frogs across all life stages in DNP will better assess *Bd* prevalence.

Acknowledgments.—Funding was provided by the Denali Foundation and Denali Education Center. National Park Service staff at Denali National Park provided support including L.Tyrell, T. Meier, B. Burnell, B. Napier, C. Lane, M. Nickley, J. Caufield, H.and P. Hassinger, D. Tomeo, Cotton, and Steve. We thank J. and S. Hamm, L. and L. Cole, W. and J. Cole of Camp Denali and North Face Lodge for logistical support and allowing surveys of their property, H. Anderson, M. Reeves, M. Purdue, D. Metcalf, A. Ambros, A. Schwaub, D. Saffir, Z. Huff, and P. Hassinger for field assistance, C. Crisafulli, G. Hokit, D. Olson, H. Shuford, C. Shuford, C. Apodaca, J. O'Donnell, and E. Lund for logistical support and equipment, and S. Kim Martin, DVM, for x-rays. The manuscript was improved by comments from M. Reeves, D. Olson, H. Purdom, V. Vredenburg, and one anonymous reviewer. K. Christiansen assisted with Fig. 1. All animals in this study were treated in compliance with institutional animal care guidelines. We obtained appropriate research permits to do this work.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 39, Number 1 (March 2008).

CAUDATA — SALAMANDERS

LISSOTRITON VULGARIS (Smooth Newt). **PREY.** *Lissotriton vulgaris* is a widespread species in Europe and western Asia. Because of their nectonic lifestyle (Dolmen 1983. J. Herpetol. 17:23–31), adult *L. vulgaris* feed primarily on planktonic Crustacea (Dolmen and Koksvik 1983. Amph.-Rept. 6:133–136). The following observations were made on 5 May 2007 between 1500 and 1545 h at an artificial pond in northern Hesse, Germany (51.2069444°N, 9.0722222°E; elev. 330 m). An adult female *L. vulgaris* (ca. 95 mm TL) was observed to capture a large dragonfly nymph (total length about 50 mm, family Aeshnidae). The nymph, which was sitting on a floating leaf, had recently moulted and the chitin armor appeared to be soft. The newt approached the leaf from beneath and captured the insect with a quick bite into its anterior portion. Another female *L. vulgaris* appeared and snapped several times at the legs of the nymph. The intruder took the prey from the other female and disappeared into deeper water, holding the nymph between its jaws. Whether the newt succeeded in swallowing its prey remains unknown. Because of their size and usually protective exoskeleton such large dragonfly nymphs may not form a regular part of the diet of *L. vulgaris* (Avery 1986. Oikos 19:408–412).

Submitted by **ANDREAS HERTZ**, Forschungsinstitut Senckenberg, Senckenberganlage 25, 60325 Frankfurt am Main, Germany; e-mail: ahertz@senckenberg.de.

NECTURUS MACULOSUS (Red River Mudpuppy). **HOST.** Several species of leeches have been known to prey upon amphibian species (Briggler et al. 2001. J. Freshwater Ecol. 16:105–111; Moser et al. 2005. J. North Carolina Acad. Sci. 121:36–40; Sawyer 1972. Illinois Biol. Monogr. 46:1–46). The leech, *Placobdella cryptobranchii* (Ozark Hellbender Leech) was described in 1977 (Johnson and Klemm 1977. Trans. Amer. Micros. Soc. 96:327–331). To date, the only known host for *P. cryptobranchii* is the Ozark Hellbender, *Cryptobranchus alleganiensis bishopi* (Moser et al. 2006. J. Arkansas Acad. Sci. 60:84–95). Herein, we provide information on the first report of *P. cryptobranchii* on *Necturus maculosus*.

On 1 Sept 2005, four juvenile *P. cryptobranchii* were found attached to a *N. maculosus* captured on the Eleven Point River, Oregon County, Missouri, USA. The *N. maculosus* appeared healthy (mass 105 g; SVL 16.5 cm; TL 25.5 cm). While attached to the *N. maculosus*, all four leeches exhibited a reddish colored crop area that indicated blood feeding upon the host. Two leeches were collected and deposited at the National Museum of Natural History, Smithsonian Institution, Washington DC (USNM 1100749) where blood-feeding was further confirmed by full crops in each leech (WEM, pers. obs.). This account is the first report of *P. cryptobranchii* feeding on *N. maculosus*, and the second known host for *P. cryptobranchii*. More information should be collected on *P. cryptobranchii* to determine if its presence on *N. maculosus* is a common occurrence or an isolated event. Since 2005, surveyors have captured 6 *N. maculosus* from the Eleven Point River in Missouri and this is the only instance when *P. cryptobranchii* was observed. With the continued decline of the main host, *C. a. bishopi*, this leech may need to rely increasingly upon *N. maculosus*.

We extend our thanks to M. Allen, G. Cravens, G. Smith, R. Rimer, and P. Veatch for assistance in the field.

Submitted by **JEFFREY T. BRIGGLER**, Missouri Department of Conservation, 2901 W. Truman Blvd, Jefferson City, Missouri 65109, USA (e-mail: jeff.briggler@mdc.mo.gov); and **WILLIAM E. MOSER**, Department Invertebrate Zoology, National Museum of Natural History, Smithsonian Institution, Washington, DC 20013-7012, USA (e-mail: moserw@si.edu).

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). **LEECH INFESTATION**. Glossiphoniid leeches (*Placobdella picta*) have previously been reported to infest Red-spotted Newts, *Notophthalmus v. viridescens* in Maryland (Mock 1987. J. Parasitol. 73:730–737), New York (Barrow 1953. Trans. Amer. Microsc. Soc. 72:197–216; Pough 1971. Science 174:1144–1146), Pennsylvania (Raffel et al. 2006. J. Parasitol. 92:1256–1264), and Virginia (Gill 1978. Ecol. Monogr. 48:145–166). To our knowledge, *P. picta* has not been reported from *N. v. louisianensis*.

On 22 March 2007, D.J. visited a fishless pond with rooted aquatic vegetation situated in an oak-hickory forest of mountainous terrain, 1 km W St. Hwy. 23, Carroll County, Arkansas. Sixty-three *N. v. louisianensis* were collected and examined for leeches; 18 (29%) had *P. picta* firmly attached to their integument, the majority under their lip, while others had leeches attached to the tail and lower abdomen. On several occasions, newts were observed trying to physically remove leeches by biting at their tails and shaking their heads vigorously, unusual behavior previously reported in *N. v. viridescens* by Gill (*op. cit*.). The same site was revisited about 2 months later on 19 May 2007 and 49 *N. v. louisianensis* were examined; only three (6%) possessed leeches. This observation further supports the understanding that *P. picta* is a temporary ectoparasite on amphibians and may be an important regulator of certain populations (Brockleman 1969. Ecology 50:632–644; Berven and Boltz 2001. Copeia 2001:907–915).

We document herein the first report of *P. picta* infesting *N. v. louisianensis*. Interestingly, this leech has previously been reported on other amphibians in northern Arkansas (McAllister et al. 1995. J. Helminthol. Soc. Washington 62:143–149; Briggler et al. 2001. J. Freshwater Ecol. 16:105–111; Turbeville and Briggler. 2003. J. Freshwater Ecol. 18:155–159; Moser et al. 2006. J. Arkansas Acad. Sci. 60:84–95).

Voucher specimens of *P. picta* are deposited in the American Museum of Natural History (AMNH 5427); a voucher of *N. v. louisianensis* is deposited in the Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 30705).

We thank the Arkansas Game and Fish Commission for Scientific Collecting Permits 032920062 and 042320071 issued to C.T. McAllister. We also thank S.E. Trauth (ASUMZ) and S.C. Watson (AMNH) for curatorial assistance.

SIDDALL**, Division of Invertebrate Zoology, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024, USA (e-mail: siddall@amnh.org).

PSEUDOEURYCEA LEPROSA (Leprous False Brook Salamander). **REPRODUCTION**. There are ca. 26 species in the genus *Pseudoeurycea* that occur in Mexico, but data on reproduction exist only for eight of those species. *Pseudoeurycea leprosa* is one of the most abundant and broadly distributed species in Mexico, inhabiting the mountains of the central part and east of Eje Neovolcánico, from Pico de Orizaba to Serranía del Ajusco (Vega and Alvarez 1992. Act. Zool. Mex. 15:1–25). The habitat of *P. leprosa* is mainly pine forest, under decomposing logs, piles of dead vegetation, or under rocks. Reproduction in this species is mostly unknown. On 14 March 2005, at Parque Nacional Zoquiapan y Anexas, where the vegetation is dominated *Pinus hartwegii*, ALV observed a mature female *P. leprosa*, (19°27'4"N, 98°41'5"W; 3433 m elev.) under a log. The female (78 mm TL) was wrapped around a ball-shaped clutch of 10 eggs. The eggs were slightly oval, with a maximum diameter of 5 mm and the minimum of 4.9 mm. Nine eggs were attacked by fungus and only one egg hatched a month later (15 April), the hatchling measured 25 mm TL.

We thank the authorities of the Parque Nacional Zoquiapan who allowed us access to their facilities. Xóchitl Aguilar-Miguel verified identification of the salamander.

Submitted by **ANGELICA LIZARRAGA-VALENCIA,** Laboratorio de Herpetología, Instituto de Biología, Universidad Nacional Autónoma de México, A.P. 70-153, México D.F. 04510 (e-mail: alizarraga@ibiologia.unam.mx); **GUSTAVO CASAS-ANDREU**, Laboratorio de Herpetología, Instituto de Biología, Universidad Nacional Autónoma de México, A.P. 70-153, México D. F. 04510; and **XOCHITL AGUILAR-MIGUEL**, Centro de Investigación en Recursos Bióticos, Facultad de Ciencias, Universidad Autónoma del Estado de México, Instituto Literario #100, 50000, Toluca, Estado de México, México.

ANURA — FROGS

CRAUGASTOR BERKENBUSCHII (Berkenbusch's Robber Frog). **MICROHABITAT USE**. *Craugastor berkenbuschii* has been reported as a common nocturnal species in the Los Tuxtlas rainforest (Vogt et al. 1997. *In* Gonzáles-Soriano et al. [eds.], Historia Natural de Los Tuxtlas, pp. 507–522. UNAM México). Some changes have recently been reported in Los Tuxtlas' concerning the herpetofaunal species abundance (Urbina-Cardona et al. 2005. *In* Halffter et al. [eds.], Sobre Diversidad Biológica: El significado de las Diversidades Alfa, Beta y Gamma, pp. 191–207. Vol. 4. Editorial Monografías Tercer Milenio, Zaragoza, España). To date there is little natural history information for *C. berkenbuschii*.

During six sampling seasons, between June 2003 and April 2005, I surveyed 108, 50 m permanent transects across the tropical rainforest at Los Tuxtlas, Veracruz, Mexico (18°32'N, 95°6'W). During 1007 person-hours of effort I recorded only a single adult *C. berkenbuschii* (80 mm SLV) in the tropical rainforest interior (100 m from the forest edge) on 31 July 2003 at 2350 h. This individual was located in the biggest forest fragment (472 ha), at 200 m elevation. Microhabitat characteristics were: in a hole in the soil 38 cm deep, 25°C soil temperature, 88% relative humidity, 62% leaf litter cover, 7 cm leaf litter depth, 40% herbaceous cover, 6.2% understory density, and 44.7% canopy cover. On 23 April 2005 at 2030 h in the second biggest forest fragment in the region (177 ha), and during the last survey night of the last field season I found a small congregation of *C. berkenbuschii* with 3 adults (72 mm average SVL) and 10 juveniles (22 mm average SVL). These individuals were in a 2 m^2 area surrounding an almost dried stream in the forest interior (200 m from the forest edge). Microhabitat characteristics at this site were: 25°C air temperature, 83% relative humidity, 90.5% leaf litter cover, 8.25 cm leaf litter depth, 30% herbaceous cover, 4.4% understory density, and 46.9% canopy cover.

This is the first report on habitat use by this species, which has been listed as Near Threatened (Santos-Barrera and Flores-Villela 2004. *In* 2006 IUCN Red List of Threatened Species. <www.iucnredlist.org>. 10 August 2007). *Craugastor berkenbuschii* should be placed on the "Los Tuxtlas forest interior species list" reported by Urbina-Cardona et al. (2006. Biol. Cons. 132:61–75). This population has been identified as fragile and may experience regional extinction. Thus, the extinction risk ranking of this species should be reconsidered because of its endemism, small range, and natural rarity. It is of special concern in the Los Tuxtlas region because of the increase in anthropogenic activities and habitat loss that continuously threaten the persistence of amphibians in the forest.

I thank Adriana González-Hernández for the species identification and help with my dissertation fieldwork. I thank Victor Hugo Reynoso for advice and support during the project, and Georgina Santos-Barrera for review of this note.

Submitted by **J. NICOLÁS URBINA-CARDONA,** Departamento de Biología Evolutiva, Facultad de Ciencias – Universidad Nacional Autónoma de México, A.P. 70-399, C.P. 04510, México, D.F.; e-mail*:* nurbina@yahoo.com.

HYPSIBOAS FABER (Smith Frog). **DIET.** *Hypsiboas faber* is a large hylid frog allocated to the *H. faber* group (Faivovich et al. 2005. Bull. Amer. Mus. Nat. Hist. 294:1–240) that occurs from northern Argentina to eastern Brazil, in permanent ponds in the Atlantic Forest Domain (Ab'Saber 1977. Geomorfologica 52:1–21; Martins 1993. Herpetol. J. 3:31–34). Published studies regarding the diet of *H. faber* are restricted to two papers that reported the major prey items are opilionids and arboreal hylid frogs (*Scinax granulatus* in Solé et al. 2005. Stud. Neotrop. Fauna Environ. 40[1]:23–28 and *S. granulatus* and *Aplastodiscus perviridis* in Solé et al. 2004. Herpetol. Rev. 35:159).

On 24 Jan 2007 at ca. 2100 h a gravid female *H. faber* (SVL 85 mm) was found preying on a juvenile *Eleutherodactylus binotatus* (SVL 29 mm) in a forest fragment at the municipality of Mariana,

state of Minas Gerais, Brazil (UTM:23K 0656671/7760247; ca. 1190 m elev.). The individual was encountered 2 m above ground and away from any pond or stream with the *E. binotatus* in its mouth. Both specimens were collected and the stomach contents of the female *H. faber* were examined and contained only plant material, likely ingested incidentally. Voucher specimens of the *H. faber* (LZV 855) and *E. binotatus* (LZV 856) were deposited in Laboratório de Zoologia dos Vertebrados of Universidade Federal de Ouro Preto (LZV/UFOP).

Eleutherodactylus binotatus is a medium-sized frog of the family Brachycephalidae occurring in Atlantic forests from Bahia to southeastern Brazil (Ribeiro et al. 2005. Biota Neotrop. 5[2]:1–15) and is found usually on the leaf litter and in low vegetation (Heyer 1990. Arq. Zool. 31[4]:237–410). This is the first record of a brachycephalid and of a terrestrial anuran being predated by *H. faber*.

Submitted by **FELIPE SÁ FORTES LEITE,** Classe Construções e Meio Ambiente, Rua Almirante Tamandaré, 438, CEP 30430-120, Belo Horizonte, MG, Brazil; **TIAGO LEITE PEZZUTI** and **LEANDRO DE OLIVEIRA DRUMMOND**, Laboratório de Zoologia dos Vertebrados, Universidade Federal de Ouro Preto, CEP 35400-000, Ouro Preto, MG, Brazil (e-mail: pjandaia@yahoo.com.br).

HYPSIBOAS FABER (Smith Frog). **PREDATION**. Predation is a major cause of mortality among tadpoles (Calef 1973. Ecology 54:741–758), and aquatic invertebrates often are cited as tadpole predators (Eterovick and Sazima 2000. Amphibia-Reptilia 21:439–461). Herein, we report predation by the belostomatid *Lethocerus melloleitaoi* on a *Hypsiboas faber* tadpole.

On 18 April 2006 at 2100 h (air temp. 12° C, water temp. 20°C) we found a *H. faber* tadpole (Gosner Stage 25; 34 mm TL) (Gosner 1960. Herpetologica 16:183–190) on the edge of permanent pond in Botucatu, State of São Paulo, Brazil (22°50'S, 48°25'W), being preyed upon by the water bug, *L. melloleitaoi* (68.1 mm body length; 25 mm width). The water bug was holding the tadpole on the anterodorsal region of the body (Fig. 1). The animals were captured and preserved. The tadpole had a cut on the side of its spiracle, caused by the belostomatid proboscis. The water bug is deposited in the entomological collection of the Museu de Zoologia of the Universidade de São Paulo, Brazil, and the tadpole is deposited at the Jorge Jim Collection, Departamento de Zoologia, Universidade Estadual Paulista, Botucatu, São Paulo State, Brazil (without numbers).

FIG. 1. *Hypsiboas faber* tadpole predated by *Lethocerus melloleitaoi.*

We thank C. Campaner for identification of the belostomatid and I. Martins for suggestions on the text. Sacae Watanabe permitted our fieldwork at the Recanto Ecologico, and S. Watanabe and CNPq provided financial support (S.C. Almeida, proc. 141733/2006-3).

Submitted by **SILVIO CÉSAR DE ALMEIDA** (e-mail: scesar@ibb.unesp.br), **DANIEL CONTIERI ROLIM**, **DOMINGOS GERALDO SCARPELLINI JÚNIOR**, and **JORGE JIM**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, 18618-000, Botucatu, SP, Brazil.

ISCHNOCNEMA HOEHNEI (Hoehnei's Robber Frog). **ADVERTISEMENT CALL**. *Ischnocnema hoehnei* was described from Paranapiacaba, in the coastal Atlantic Forest of the state of São Paulo, southeastern Brazil (Lutz 1958. Mem. Oswaldo Cruz, Rio de Janeiro, 56:378). It has also been observed at Boracéia, (Heyer et al. 1990. Arq. Zool., São Paulo, 31:231–410) and Teresópolis, ca. 400 km NE of the type locality in the state of Rio de Janeiro (http://www.globalamphibians.org/servlet/GAA).

On 29 Nov 1997 AAG observed the species at its type locality. Two males were heard calling, although only the call of a single individual was recorded. This call was recorded with a UHER 4200 (19 cm/s) tape recorder and a UHER M518A Microphone. The call was digitized and audio spectrogram prepared with the Spectrogram software (Horne 1994. Spectrogram. www.visualizationsoftware.com/gram.html). Sample rate was set at 22050 Hz, with 16-bit resolution. The call was analyzed and oscillogram and spectrogram derived with the SoundRuler software (Griddi-Papp 2007. Sound Ruler. V0.9.6.0. http://soundruler.sourceforge.net), using a Fast Fourier Transformation at 1024 data points, frequency resolution at 21.5 Hz, and low and high band limit at 50 and 7500 Hz. The individual recorded was calling on the ground in an open area, among tuffs of grass-like plants (40 cm tall) about 8 m from the forest border. The other calling individual was about 10 m away in similar habitat. Calls were released sporadically. The recorded call (Fig. 1) presented 50 pulses and lasted 1.3 s; pulses lasted 0.025–0.035 s; pulse rate was 2123/s. Call frequency and intensity modulated, beginning low and quiet, rising in frequency and intensity to about mid-call, then maintaining relatively constant frequency and intensity to the end; 4th to 13th note frequency ranging from 1591 to 1980 Hz; second half of call with frequencies between 720 to 2900 Hz; side bands evident. *Ischnocnema hoehnei* has traditionally been allocated to the *E. binotatus* species group (Lynch and Duellman 1997. Nat. Hist. Mus., Univ. Kansas Spec. Publ. 23:1–236), although Heinicke et al. (2007. PNAS. 104[24]:10092–10097) reported *E. binotatus* only distantly related to the other eleutherodactylines of southeastern Brazil. Acoustic data, such as presented here, might help resolve the species group relationships among the eleutherodactyline frogs of southeastern Brazil.

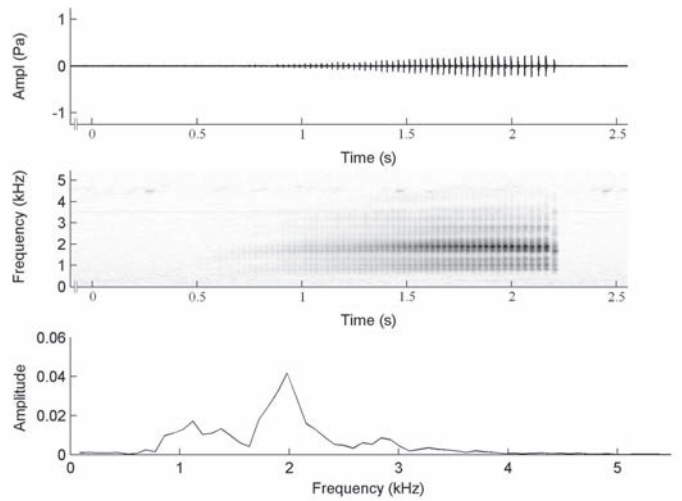

FIG. 1. Oscillogram, spectrogram, and power spectrum of the call of *Ischnocnema hoehnei*, Paranapiacaba, São Paulo, Brazil, air 16.5°C. Voucher: AmphibiaWeb photo (CalPhotos ID: 0000 0000 0504 0973); call also available in the AmphibiaWeb (unnumbered MP3 sound file).

KALOULA PULCHRA (Painted Burrowing Frog). **ANTIPREDATOR BEHAVIOR**. *Kaloula pulchra* is known from northern India (Meghalaya) east into Vietnam (IUCN, Conservation International, and NatureServe 2006. Global Amphibian Assessment. <www.globalamphibians.org>. Accessed 15 June 2006). *Kaloula pulchra* occurs throughout Thailand (Nabhitabhata et al. "2000" 2004. Checklist of Amphibians and Reptiles in Thailand. Office of Environmental Policy and Planning. 152 pp.) and is often used for human consumption. To our knowledge, antipredator behavior in *K. pulchra* is poorly known and no antipredator behavior has been described from Thailand. On 29 March 2003 during our visit to Sam Pran Protected Unit, Khao Ang Rui Ni Wildlife Sanctuary, Tha Takhieb District, Chachoengsao Province (southeastern Thailand), we had an opportunity to photograph frogs that had been collected for food. While being handled during the daytime, an individual frog displayed an antipredator behavior when touched. The frog inflated its lungs and outstretched the limbs. It presented a large color pattern image on its dorsum. The inflation of the lungs did not lift the body. When we overturned the frog the lungs remained inflated and the individual remained rigid and immobile for several seconds (Fig. 1). Anurans frequently employ posture as a defensive mechanism, and in species of *Scaphiopus*, *Limnodynastes*, *Leptodactylus*, and *Bufo*, inflation of the lungs is usually accompanied by elevation of the body from the substrate (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill Book Company, New York. 670 pp.).

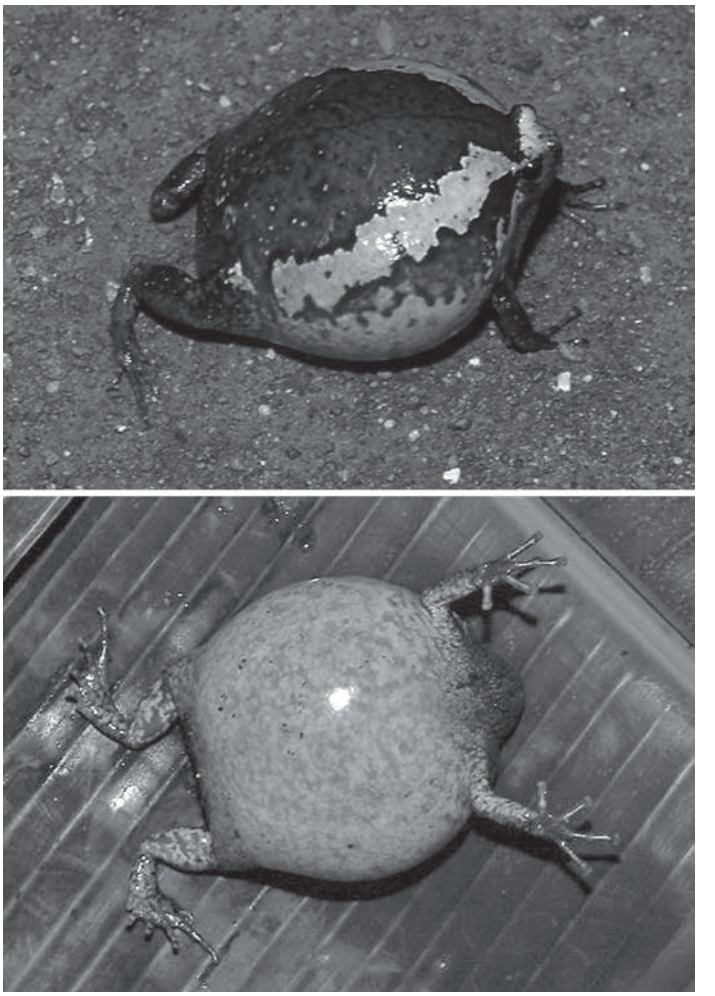

FIG. 1. Top: Dorsolateral view of *Kaloula pulchra*, showing antipredator behavior. Lower: Ventral view.

We thank Anton Russell and Sutee Duangjai for their editorial assistance.

NECTOPHRYNE BATESII (Bates' Tree Toad). **JUVENILE COLORATION.** Marked differences in the coloration and pattern between juvenile (i.e., recently metamorphosed) and adult anurans are seldom noted in the literature. In most cases, this is because there are few remarkable differences between different age classes. *Nectophryne* comprises two species found in Central African forests extending from the coast of Cameroon, Equatorial

Guinea, and Gabon across to northeastern Democratic Republic of Congo (IUCN et al. 2006. <www.globalamphibians.org>). Recently metamorphosed juveniles of *N. afra* are velvet black with thin bluish white lines that cover much of the dorsal surface and form loops or even rings (Scheel 1970. Rev. Zool. Bot. Afr. 81:225–236). In contrast, adult *N. afra* are black or brown with dorsolateral bands that extend posteriorly from the eyes to the inguinal region and are lighter shades of brown or yellow. There are no reports of similar ontogenetic changes in color or pattern in *N. batesii* or the closely related Cameroonian toad genus *Wolterstorffina*.

In June 2006, juvenile *Nectophryne* specimens, MCZ A-138204 (SUL 5.6 mm) and 138144 (SUL 6.9 mm), were collected by VD from leaves and branches surrounding orchids in moist, tropical, submontane forest near Bidjouka (3.1430556°N, 10.4775°E) and Akom 2 (2.7444444°N, 10.5305556°E), in Sud Province, Republic of Cameroon. These specimens exhibit a color pattern similar to each other but different from *N. afra* juveniles. The specimens are identifiable as *Nectophryne* because both exhibit lamellae on the hands and feet, which are a unique, derived characteristic of this genus. To determine the species identity of these specimens, a genomic region consisting of 2365 base pairs of the mitochondrial 12S and 16S ribosomal RNA, and intervening Valine tRNA, was amplified from MCZ A-138144 (Genbank [GB] No. EU394537) and compared to sequence data from the same genomic region of adults of both *N. afra* (MVZ 234685, GB EU394535; MVZ 234686, GB EU394533; CAS 207832, GB EU394534; GB DQ283360) and *N. batesii* (MVZ 234687, GB EU394536; GB DQ283169). Sequences were aligned in Clustal X v.1.83.1 using default parameters and uncorrected pairwise sequence divergences calculated using PAUP v.4.0b10. The mean pairwise divergence found within *N. afra* is 0.83% (range: 0.17–1.59%; N = 6 pairwise comparisons) and the pairwise divergence between the two *N. batesii* specimens is 6.67%. The mean divergence between *N. afra* and *N. batesii* is 10.80% (range: 10.08–11.23%; N = 8 pairwise comparisons). The mean pairwise divergence between the juvenile specimen (MCZ A-138144) and *N. afra* is 10.25% (range: 10.05–10.81%), whereas it is only 4.32% and 4.67% from the two *N. batesii* specimens. Because the latter are less than the divergence between the two *N. batesii* adults and fall within the range of intraspecific divergence in 16S rRNA documented in other anurans (i.e., Vences et al. 2005. Front. Zool. 2:1–12), it is reasonable to assign these juvenile specimens to *N. batesii*. Similar results were obtained by local BLAST searches in BioEdit v.7.0.5.

The juvenile specimens were compared to adults of both *N. afra* (MCZ A-2607, A-101156–59; MVZ 234685–86) and *N. batesii* (MCZ A-46621, A-101155; MVZ 234687). In dorsal view, juvenile *N. batesii* are black with four prominent and solid transverse stripes that are distributed at roughly equal intervals across the rostrocaudal axis. In life, these stripes are pale light green and change to either gray or white in preservative. In addition to the dorsal stripes, there is a white stripe extending proximodistally on the posterodorsal surface of the femur, a small transverse stripe at both the proximal and distal ends of the tibiofibula, and a spot at the most proximal part of the tarsus. The throat is somewhat darkened but the belly exhibits little, if any, pigmentation. Only one of the adult *N. batesii* examined (MCZ A-101155) exhibits any markings that can be interpreted as similar to the juveniles. However, these are only apparent as very poorly defined lighter regions on the dorsal surface in the approximate position of the four transverse stripes. Relatively little is known of the natural history of *Nectophryne* (Scheel 1970, *op. cit.*). The function, if any, of the strikingly different coloration and pattern of juveniles and adults remains enigmatic. Future study should focus on whether this distinctive juvenile coloration plays a role in crypsis, mimicry, or possibly aposematism.

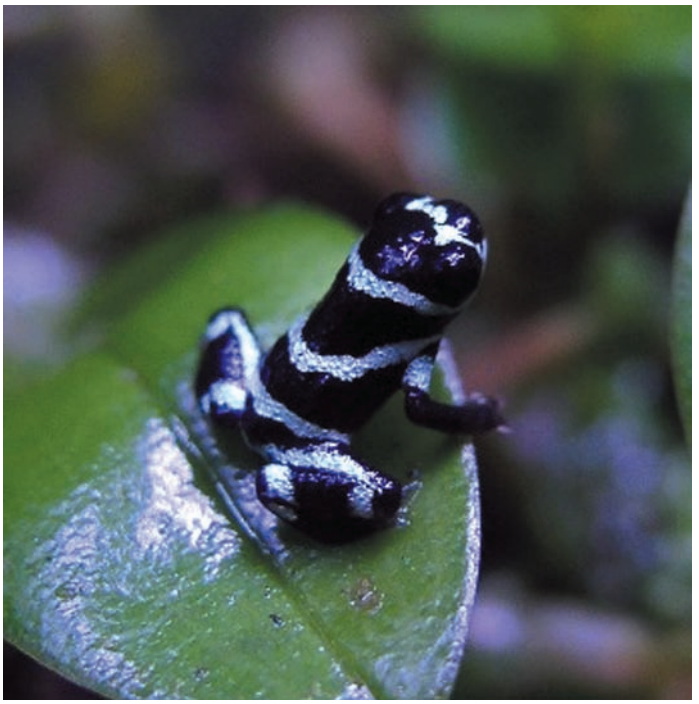

FIG. 1. Juvenile *Nectophryne batesii* (MCZ A-138144), photographed in life, exhibit coloration and pattern that differ remarkably from adults.

PHYSALAEMUS CUVIERI (Barker Frog). **PREDATION.** Although anuran amphibians are often preyed upon by invertebrates, including spiders of the family Ctenidae (Toledo 2005. Herpetol. Rev. 36:395–400; Menin et al. 2005. Phyllomedusa 4:39–47), the taxonomic extent and size aspects of that relationship remain poorly documented. We observed a relatively small ctenid spider preying on a *Physalaemus cuvieri* at 2152 h, 1 Jan 2007, on the property of Escola Evangelica Buriti (5.4066667°S; 55.8030556°W), ca. 7 km W of Chapada dos Guimarães on Hwy MT251, Mato Grosso State, Brazil. The female spider (0.8 g) was obliquely head-up on a lichen- and moss-covered sapling (dbh 3 cm), ca. 1.2 m above the ground near a small stream, with the male *P. cuvieri* (SVL 29 mm; mass 1.8 g; CFBH 14277, Coleção de Anuros, UNESP Rio

FIG. 1. Adult *Physalaemus cuvieri* restrained in the chelicerae of an unknown species of ctenid spider. The *P. cuvieri* was more than two times the weight of the spider.

Claro, São Paulo, Brazil) restrained in its chelicerae. The frog was immobile but not limp, bleeding slightly from its wounds, and responded to human handling with faint leg movements. The impressively high prey/predator mass ratio (2.25) was likely facilitated by venom injection, a specialized predation tactic (Toledo et al. 2007. J. Zool. 271:170–177). *Physalaemus cuvieri* is typically terrestrial so perhaps the spider captured the frog on the ground and then carried it up the tree, after immobilizing it with venom. The ctenid is likely an undescribed species in an as yet undetermined genus of Cteninae (Daniele Polotow, pers comm.), and is deposited in the arachnology collection of Insituto Butantan, São Paulo, Brazil (IBSP 85314).

PHYSALAEMUS CUVIERI (NCN). **PREDATION**. On 26 Dec 2006 at 2145 h in Eldorado City (26°24'32"S, 54°34'56"W), Misiones Province, Argentina, we found a dead adult male *Physalaemus cuvieri* (26.7 mm TL) caught by a giant water bug *Lethocerus annulipes* (Belostomatidae: Lethocerinae) (67.0 mm TL) (Fig. 1) in a shallow temporary pond surrounded by tall grasses. There were several calling males on the edge of the pond, and a foam nest was observed, indicating reproductive activity of *P. cuvieri*. Predation of adult anurans by Belostomatinae giant water bugs was previously reported by Oda (2006. Herpetol. Rev. 37:4) and Toledo (Phyllomedusa 2:105–108). To our knowledge, this is the first report of a Lethocerinae giant water bug predating an adult *P. cuvieri*.

Fig. 1. *Physalaemus cuvieri* predated by *Lethocerus annulipes* in Eldorado city, Misiones, Argentina.

We thank G. C. Küppers for her comments on the manuscript and for assistance in the field, and to J. Muzón for help identifying the giant water bug.

***PROCERATOPHRYS* SP.** (NCN). **PREDATION.** An undescribed Cerrado species of the genus *Proceratophrys* belongs to the *cristiceps* group, and is found in open grasslands and in gallery forests (R. Brandão, pers. comm.). On 12 March 2002, at Fazenda Água Limpa, Distrito Federal, Brazil four adult White-eared Puffbirds (*Nystalus chacuru*) were captured on mist nets in a "campo cerrado" area. One of them was holding a *Proceratophrys* sp. in its beak (Fig. 1). This puffbird is known to dig in ground or banks to construct a gallery as an entrance for the nest chamber, and could have captured the frog in its diurnal retreat. The White-eared Puffbird is a common Cerrado species that is considered mostly insectivorous, although other food items, including lizards and vegetable matter, have been reported (Del Hoyo et al. 2002. Handbook of the Birds of the World. Cotingas to Pipits and Wagtails. Lynx Edicions, Barcelona). This is the first record of *Proceratophrys* being preyed upon by a White-eared Puffbird.

SCINAX RUBER (Red-Snouted Treefrog). **PREDATION.** It has long been known that invertebrates are predators of adult frogs (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York. 670 pp.; Hayes 1983. Biotropica 15:74–76). Recently, Brasileiro and Oyamaguchi (2006. Herpetol. Rev. 37:451) reported a male *Scinax alcatraz* being preyed upon by an immature Wandering Spider, *Oligoctenus medius*. Here, we report the predation of adult *Scinax ruber* by a water bug, *Belostoma* sp. (Hemiptera: Belostomidae).

On 30 March 2007, between 1900 and 2200 h, in a small temporal pond close to the Coello River in Tolima, Colombia (4.25°N, 75.32°W), we observed three *Belostoma* sp. grasping frogs in the inguinal region to kill them (Fig. 1). This observation of high predation in a short time coincides with the beginning of the rainy season and the explosive reproductive behavior of *S. ruber*.

SPHAENORHYNCHUS DORISAE (Spotted Hatchet-faced Treefrog). **OCULAR ANOMALY**. There are no reports in the literature regarding ocular anomaly in *Sphaenorhynchus dorisae*. On 18 May 2006 at 1050 h we observed an adult female *S. dorisae* (INPA-H 17704; SVL 28.3 mm, mass 2.8 g), without the visual organs, in the Reserva Extrativista do Baixo Juruá (03.60194°S, 066.06711°W), Amazonas, Brazil. We found the specimen in the margin of flooded forest near a branch 1.5 m above ground, at Igarapé Central. The ocular cavities were covered only with a fine membrane (Fig. 1).

We are grateful to IBAMA for financial, logistic support and research permits; we thank the inhabitants of the Reserva Extrativista do Baixo Juruá for fieldwork assistance; FAPEAM for scholarships to V. T. Carvalho; CAPES and IIEB (BECA Program, Gordon and Betty Moore Foundation) for scholarships to R. Arruda.

TESTUDINES — TURTLES

APALONE SPINIFERA (Spiny Softshell Turtle). **DIET**. *Apalone spinifera* is a generalist carnivore known to consume a variety of invertebrates and vertebrates; vegetation is also occasionally eaten, but nuts (= a single seeded fruit with a woody pericarp, partially or wholly encased in a husk) have only rarely been reported in the diet (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 578 pp.). On 22 July 2007 we captured two large (carapace length = 380 and 405 mm) female *A. spinifera* in a baited (canned sardines) hoopnet set in Bayou Duplantier, ca. 1 km downstream from the Louisiana State University Campus in Baton Rouge, East Baton Rouge Parish, Louisiana, USA. Bayou Duplantier is a turbid, low gradient stream draining an extensive urban watershed. We returned these turtles to the lab and each was placed in a water-filled plastic tub (capacity ca. 75 L) for 48 h, and then permanently marked and released at the capture site. Both turtles defecated within 24 h of capture and we passed the contents of each tub over a sieve (2-mm mesh) to recover food items. Numerous acorn (*Quercus* spp.) fragments were found in the feces of both turtles, and pieces of at least one pecan (*Carya illinoensis*) were recovered from the smaller female; other food items included cicadas (Cicadidae), crawfish (*Procambarus* sp.), grasshoppers (Caelifera), and an unidentified fish. The number of acorn fragments indicated that each turtle had consumed 5–6 of these fruits. We were unable to identify the acorns to species owing to the small size of the fragments; however, Water (*Quercus nigra*) and Live (*Q. virginiana*) Oaks are common along the bayou and produce small acorns that could be readily swallowed by turtles. Viable nuts rapidly sink (Schopmeyer 1974. Seeds of Woody Plants in the United States. USDA Forest Service, Agriculture Handbook No. 450, Washington, D.C. 883 pp.) and the fragments we recovered were darkly stained suggesting the nuts had been buried in sediments since the previous autumn and probably consumed as turtles foraged among the benthos. Our observation compliments an earlier report from Iowa (Williams and Christiansen 1981. J. Herpetol. 15:303–308) where 61% of *A. spinifera* stomachs contained plant material, including "acorns, leaves, and vegetable matter" (specific breakdown not provided). To our knowledge, these are the only two reports of *A. spinifera* consuming acorns. We are unaware of any previous report documenting pecan consumption by *A. spinifera*. *Apalone spinifera* are known to forage extensively among benthic debris (*op. cit.*) and consumption of nuts is therefore not unexpected. Acorns and pecans represent a concentrated source of carbohydrates and fat and also contain relatively high levels of protein, calcium, and phosphorus (Goodrum et al. 1971. J. Wildl. Manage. 35:520–532). Sloan et al. (1996. Chelon. Conserv. Biol. 2:96–99) found intact acorns and pecans in the stomachs of *Macrochelys temminckii* and raise the possibility that these turtles function as seed dispersal agents in riparian ecosystems. However, our observations, albeit limited, indicate that *A. spinifera* are seed predators rather than seed dispersers because nuts are digested instead of being passed intact through the digestive tract.

We thank Mike Leggio, Charles Hardin, and Paul Spence for field assistance during the summer 2007. Facilities for processing turtles were kindly provided by George S. Platt.

APALONE SPINIFERA ASPERA (Gulf Coast Spiny Softshell). **PREDATION.** The Flathead Catfish, *Pylodictis olivaris*, is an obligate omnivore; adults are primarily piscivorous and young consume invertebrate prey. Native to the Rio Grande, Mississippi, and Mobile River drainages, *P. olivaris* has been introduced to other drainages beyond their native ranges in North America. Where introduced, they are considered an invasive species due to their heavy predation on native fish species and associated population declines (Pine 2005. Trans. Am. Fish. Soc.134: 901–909). During the summer of 2007, *P.olivaris* were captured on Ichawaynochaway Creek at the J.W. Jones Ecological Research Center (31.367°N, 84.800°W, Newton, Georgia) for a study examining the impacts of this species on native aquatic fauna. Stomach contents were examined and in one male *P. olivaris* (1016 mm TL; 13.3 kg) a partially digested *A. spinifera* was found. Much of the turtle was intact, enabling identification and measurements (carapace length 130 mm; width 128 mm; plastron length 109 mm; width 123 mm). Flathead Catfish at this size predominately feed on live fishes such as Centrarchidae (sunfish) and Percidae (perches and darters) in addition to decapods (crayfish). Known predators of *A. spinifera* include fishes, other turtles, snakes, alligators, wading birds, and small mammals (Webb 1962. Univ. Kansas Publ. Mus. Nat. Hist. 13:429–611). To our knowledge, this is the first record of turtles in the diet of *P. olivaris* in the southeastern U.S.

CHELODINA LONGICOLLIS (Eastern Long-necked Turtle). **DRINKING BEHAVIOR**. Most species of freshwater turtles use terrestrial habitats at several points in their annual and life cycles, including nesting, movements between water bodies, and, in some species, for over-wintering and aestivation. Some of these behaviors require an extended time out of water (i.e., weeks, months, or even years) and thus present a challenge for the maintenance of water balance. During a radio-telemetric study of *C. longicollis* in

Booderee National Park, Jervis Bay Territory, Australia, I observed one obvious and two apparent instances of terrestrial drinking behavior during a rainfall event (44.2 mm) on 20 February 2005 in the austral summer. All three turtles (2 male, 1 female; carapace lengths 170.0–215.5) had been inactive and completely buried under leaf litter in the forest near a wetland that had been dry for 93 days, but between 1649–1655 h during heavy rainfall at 20°C, all three were observed on the surface within one meter of their refuge sites. Two turtles were in a sprawled posture with legs and neck fully extended, while the third was actively drinking water that had pooled in a shallow natural depression in the litter. The turtles were buried in their previous refuge sites the following day. During drought, terrestrial tortoises are well known for their ability to drink pooled water during rainstorms (Medica et al. 1980. Herpetologica 36:301–304), but this is apparently the first report for drinking in a freshwater turtle while in natural terrestrial aestivation. Such behavior may in part replace respiratory and evaporative water losses incurred throughout aestivation and allow for more extended periods of survival out of water.

CHELONIA MYDAS (Green Sea Turtle). **HABITAT AND OCCURRENCE.** Of the seven recognized sea turtle species, five are known to visit the coastline of Brazil to feed and nest (Marcovaldi 1999. Marine Turtles of Brazil: The History and Structure of Projeto TAMAR-IBAMA. Biological Conservation. 35 pp.). The region of Cananéia, at the southernmost part of the state of São Paulo, southeastern Brazil, is a complex of conservational units visited by marine turtles year round, particularly the *Chelonia mydas*, which uses this region to feed and grow (Bondioli et al. 2005. *In* II Jornada de Conservação de Pesquisa de Tartarugas Marinhas do Atlântico Sul Ocidental, Praia do Cassino, Rio Grande do Sul. Livro de Resumos. 53 pp.). In this area, there are artisanal fishing traps called "cerco-fixo" or permanent fencing. These traps incidently capture the turtles, maintaining them alive. Since 2003, monitoring of the region's beaches, as well as the "cerco-fixo" distributed along the entire estuary, has allowed us to register the occurrence of 222 marine turtles. Of these, 216 were Green Sea Turtles (1% adults, with a curvilinear length of the top shell > 70 cm, and 99% juveniles), one subadult Leatherback Turtle (*Dermochelys coriacea*), two subadult Hawksbills (*Eretmochelys imbricata*), five Loggerhead Sea Turtles (*Caretta caretta*, two subadults and three adults), and the carcass of an adult Olive Ridley Sea Turtle (*Lepidochelys olivacea*). Of the 222 turtles, 177 (all juvenile Green Turtles) were collected in the "cerco-vivo," therefore, alive. Remaining turtles were found dead along the beaches in the region. Aside from these data, informal reports as well as shells displayed in homes, museums, and local restaurants (in approximately the same proportions registered in this study) confirm the presence of these species in this region. Based on these data, we can conclude that, besides being characterized as a feeding area for Green Sea Turtles, the Estuarine Complex Lagoon of Cananéia is visited by all the species of marine turtles which visit the Brazilian coastline. Because this region is characterized by different conservation units, its preservation also helps assure the preservation of the marine turtles that spend at least one phase of their lives in the region.

DERMOCHELYS CORIACEA (Atlantic Leatherback Sea Turtle). **REPRODUCTION**. *Dermochelys coriacea* is reported to nest along the entire eastern coast of Florida, with highest concentrations in southern Florida (Meylan et al. 1995. Sea Turtle Nesting Activity in the State of Florida. Florida Marine Research, Pub. No. 52). Herein, we provide support for these findings along with a first county record voucher. At ca. 1645 h on 26 June 2007, a female (ca. 340 kg) *D. coriacea* (UF photographic voucher 151367) came ashore on Vilano Beach ca. 4 km N of the St Augustine Inlet, St. Johns County, Florida (29.950575°N, 81.3034694°W, datum WGS84, elev. <1 m). This turtle created a disturbed area (combined nest and adjacent sand displacement) of about 4.5 × 6.1 m. The entire act was captured on film, and nesting lasted from 1645–1811 h when the turtle returned to the Atlantic Ocean. There are currently three other known nestings of *D. coriacea* in St. Johns County, all to the north of this documented nest. Only five *D. coriacea* nests have been recorded in northeastern Florida since 2004.

ERETMOCHELYS IMBRICATA (Hawksbill Sea Turtle). **PREDATION.** Predation on hatchling sea turtles by fire ants, crabs, fish, birds, and mammals is widely acknowledged, however, there are relatively few accounts of reptiles as hatchling sea turtle predators. To our knowledge, only varanid lizards and a few snakes have been reported as reptilian predators of hatchling sea turtles (Blamires 2004. Copeia 2004:370–377; Brattstrom 1955. Am. Midl. Nat. 54:219–229; Crother 1986. Herpetol. Rev. 17:47). Here we report neonate sea turtle predation by a teiid lizard, *Ameiva fuscata*, on the island of Dominica, West Indies.

At 1200 h on 6 September 2007, while walking the boardwalk at the Soufriere Scott's Head Marine Reserve at Champagne Bay we observed an adult *A. fuscata* scrambling up the coastal slope with a hatchling *Eretmochelys imbricata* in its mouth. The lizard had the dead hatchling sea turtle grasped by the head and dropped it as we followed to investigate further. We searched beneath the 1.5 m high boardwalk that runs parallel to the ocean and the coastal slope and found an *E. imbricata* nest. The nest was in a small sandy opening (ca. 20 cm diameter) among beach stones 5– 15 cm diameter. A minimum of six other *A. fuscata* were within 1 m of the nest but fled as we approached. Five live hatchlings were exposed in the ca. 12 cm wide exit burrow and after excavation we

discovered 145 live hatchlings and 36 eggs that were undeveloped or in different stages of decay. Whether the lizards were waiting for the hatchlings to emerge or digging them from the sand is unknown.

To our knowledge, this is the first reported observation of a neotropical lizard preying on hatchling sea turtles. Species of *Ameiva* are among the largest terrestrial carnivorous lizards in the Lesser Antilles and *A. fuscata* can reach mean densities of 379 individuals/ha on Dominica (Bullock and Evans 1990. J. Zool. Lond. 222:421–443). The consequences of high population densities and active foraging behavior of *A. fuscata* may have significant effects on hatchling sea turtle survival on Dominica and warrants further study wherever coastal populations of *Ameiva* are sympatric with nesting sea turtles.

We thank Alan Bolten and Karen Bjorndal for confirming the identification of the sea turtle hatchings and for providing comments on this note. This observation was made while conducting *Iguana delicatissima* research on Dominica, funded through the center for Conservation and Research for Endangered Species (CRES) at the Zoological Society of San Diego.

Submitted by **CHARLES R. KNAPP**, Conservation and Research for Endangered Species, Zoological Society of San Diego, 15600 San Pasqual Valley Road, Escondido, California 92027, USA (e-mail: cknapp@ufl.edu); and **LYNDON PRINCE**, Salisbury Village, Commonwealth of Dominica, West Indies.

GOPHERUS AGASSIZII (Desert Tortoise). **PREDATION**. Predation events on *Gopherus agassizii* are rarely observed and documented. Thus, most predators of the Desert Tortoise have been inferred by the presence of tortoise parts in scats, pellets, and/or carcasses deposited at nests or denning sites. Boarman (2002. *In* Boarman and Beaman [eds.], The Sensitive Plant and Animal Species of the Western Mojave Desert. U.S. Geological Survey, Western Ecological Research Center, Sacramento, California) records several native predators that are known to prey on Desert Tortoise eggs, hatchlings, juveniles, and adults, including Coyotes (*Canis latrans*), Kit Foxes (*Vulpes macrotis*), Badgers (*Taxidea taxus*), Skunks (*Spilogale putorius*), Common Ravens (*Corvus corax*), Golden Eagles (*Aquila chrysaetos*), and Gila Monsters (*Heloderma suspectum*).

During a four year study (2003–2006) of Desert Tortoises at a site ca. 40 km NE of Barstow, California, in San Bernardino Co. (Walde et al. 2007. Southwest. Nat. 52:147–149; Walde et al. 2007. West. N. Am. Nat. 67:147–149), we observed many Burrowing Owls (*Athene cunicularia*). Examination of owl pellets that are ejected close to burrows and perches revealed that they often contain insect remains (Lepidoptera and Coleoptera), and less frequently remains of small rodents. On 10 May 2006, a Burrowing Owl pellet was found close to a perch that had several parts of a beetle, *Cerenopus concolor* (Coleoptera: Tenebrionidae) in it, a species which frequently comprised 100% of pellets. This particular pellet, however, also contained vertebral and marginal scute material and bones of the Desert Tortoise. One vertebral scute was entirely intact and had growth annuli suggesting that the Desert Tortoise was at least one year old. The disarticulated pellet was deposited in the Natural History Museum of Los Angeles County, Los Angeles, California (LACM 168081). To our knowledge, this is the first documentation of predation by *A. cunicularia* on the Desert Tortoise.

We thank Rolf Aalbu for identification of the Tenebrionidae in the owl pellet and Rick Feeney of the Natural History Museum of Los Angeles County for his assistance with the specimen.

GOPHERUS POLYPHEMUS (Gopher Tortoise). **RECORD SIZE**. To our knowledge, the largest *Gopherus polyphemus* reported to date had a straight-line carapace length of 38.7 cm (Timmerman and Roberts 1994. Herpetol. Rev. 25:64). Here we report a specimen that exceeds this size. In March 2007, one of us (AE) received for rehabilitation a large, injured Gopher Tortoise. The cause of injury was unknown, but its wounds, which proved fatal, were consistent with damage from a backhoe shovel. The tortoise originated from Lee County, Florida, west of Interstate Highway 75, within the city limits of Fort Myers. The exact point of collection was withheld, due to the potentially illegal action which led to the discovery and death of this tortoise. Ultrasound evaluation (by O. Diaz, DVM, of Orlando, Florida) revealed testes, showing the tortoise to be male. However, the posterior plastron has an unpronounced indentation, and the anal scute is single, flat, extends toward the tail, and is not divided or curved as is normal in male *G. polyphemus*. Post mortem weight was 12.2 kg. The straight-line carapace length was 41.6 cm, and the plastron length was 40.6 cm. The specimen is preserved in the Chelonian Research Institute collection (PCHP 12633).

GRAPTEMYS FLAVIMACULATA (Yellow-blotched Map Turtle). **INTERSPECIFIC BASKING SITE COMPETITION.** *Graptemys flavimaculata* is a highly aquatic, riverine turtle endemic to the Pascagoula River and its tributaries of southern Mississippi, USA (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institute Press, Washington, D.C. 578 pp.). It is common to see multiple turtles of different species occupying the same snag within the Pascagoula River system, but there have been no reports concerning interspecific competition among turtles for basking locations in this area. Here we report observations of interspecific aggression and competitor avoidance behavior by *G. flavimaculata* when trying to secure a desired basking location.

On 17 April 2007 (1410 h), on the Leaf River (Forrest County, Mississippi), WS observed from a distance of 30 m a small *G. flavimaculata* female basking partly submerged on a low-angled tree crown snag, while a slightly smaller *Apalone mutica* was basking directly above her. The female *G. flavimaculata* extended her

forelimb and pushed the *A. mutica* off of the basking snag, then climbed to the location that the *A. mutica* had vacated. Shortly thereafter (ca. 30–45 sec), presumably the same *A. mutica* re-emerged on the same snag below the *G. flavimaculata*. Soon after the *A. mutica* emerged, a second small *G. flavimaculata* female, similar in size to the first, emerged from the bank side of the snag. While she was climbing onto the snag, she placed her right forelimb on the carapace of the *A. mutica*, apparently prompting it to move to another emergence point on the same snag (ca. 0.5 m away). After several minutes, the second *G. flavimaculata* vacated the log and then quickly reemerged and oriented itself behind the first *G. flavimaculata*.

Also on 17 April 2007 (1530 h), an alternative strategy, avoidance of a much larger interspecific, was observed by several *G. flavimaculata*. Upon approaching a 1.5 m long horizontal branch-sized snag, several emydid turtles were observed by WS vacating their basking locations before they could be identified. The snag was watched (via spotting scope) from a distance to see if the turtles would reemerge. Within minutes, a large female *G. flavimaculata* (>15 cm CL) emerged from the lowest angle of the snag/water interface and climbed approximately 15 cm up the snag. A large *Pseudemys concinna* (>20 cm CL) emerged behind the *G. flavimaculata* female and occupied the lowest emerged portion of the snag. After the emergence and 'roadblock' of the snag by the *P. concinna*, several more *G. flavimaculata* were observed swimming around the snag (heads emerged from the water). A second large *G. flavimaculata* female climbed vertically up the channel side of the snag to a basking location about 0.75 m away from the first *G. flavimaculata* female. A third *G. flavimaculata* female exhibited the same vertical climbing behavior, except approaching from the bank side of the snag and choosing a position between the first and second *G. flavimaculata*. It appeared that the second and third *G. flavimaculata* females used this technique, climbing a steeper, vertical angle, to get to a desired basking location while avoiding encounters with the previous two occupants of the snag.

In the first observation, aggression appeared to be advantageous for the larger *G. flavimaculata* females in order to obtain a favorable basking location. However, in the second observation, the two female *G. flavimaculata* 'climbers' were smaller than the *P. concinna*, and therefore, may not have had the option of using aggression to advance themselves to a favorable basking locality. These observations are supported by previous research that examined aggressive interactions among four emydids: *Trachemys scripta*, *Pseudemys concinna*, *Graptemys pseudogeographica*, and *Graptemys oauchitensis* (Lindeman 1999. J. Herpetol. 33:214–219). Lindeman noted that aggressive interactions were "won" 70% of the time by larger turtles, which is consistent with our observations and interpretations of *G. flavimaculata* behavior.

GRAPTEMYS FLAVIMACULATA (Yellow-blotched Map Turtle). **FORAGING BEHAVIOR.** The *Graptemys flavimaculata* is a freshwater aquatic turtle that is endemic to the Pascagoula River system of southern Mississippi, USA (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institute Press, Washington, D.C. 578 pp.). R. J. Brauman and R. A. Seigel (unpubl. report) suggest that the primary food items of *G. flavimaculata* are insects, sponges, mollusks, and algae. They concluded that the presence of algae was due to secondary ingestion, rather than being a primary food item. However, very little is known about the foraging behavior of this species. Here we report two separate observations of female *G. flavimaculata* foraging on algae-covered submerged logs.

On 2 June 2006 (1650 h), a female *G. flavimaculata* was observed (by WS) ca. 0.3 m deep in a swift-flowing riffle section of the Leaf River (Forrest County, Mississippi) foraging on an algae-covered log. The female was grasping the downstream side of the log with her forelimbs as she appeared to "graze" on the periphyton. After brief observation, the female was captured with a dip net for marking and measurement (16.7 cm straight-line carapace length, 740 g); she had some filamentous algae in her mouth at the time of capture.

The second observation (also by WS) occurred on 30 August 2006 in the Lower Pascagoula River (Jackson County, Mississippi) at 1340 h. An adult female *G. flavimaculata* was observed from 2–2.5 m away (the presence of the boat did not appear to affect her behavior) "grazing" on the periphyton of a submerged log, in the same manner as noted before on the Leaf River. Her forelimbs were gripping the log as she foraged on the bank side. While feeding, she would quickly protrude her head, bite, and pull with her jaws, sometimes doing a "pushup" motion with her forelimbs to assist in tearing the algae off the submerged log. Feeding appeared at random without a side-to-side or a top-to-bottom order. This foraging behavior occurred in water ca. 20–80 cm deep and continued as the turtle moved ca. 1.5 m along the log, sometimes holding onto the log with all four legs. After continuously feeding for ca. 15 minutes, the turtle surfaced (apparently for air), noticed its observer and quickly swam away. Inspection of the log showed little evidence of aquatic insects, but it was covered by a very thick layer of short growth filamentous algae. Also, while watching the adult female, a juvenile female *G. flavimaculata* was also seen foraging in a similar manner for the first 3–5 minutes of the observation.

During both of these observations it could not be ascertained if the turtles were feeding directly on algae or on macroinvertebrates within the algae. Lahanas (1982. Unpubl. M.Sc. thesis, Auburn University) found that the diet of a closely related species, *G. nigrinoda*, had 28% and 41% average volume plant material for females and males, respectively. Similar behavior hás been noted in *G. oculifera*, another closely related species (R. L. Jones, pers. comm.). Thus, based on the above observations, it is plausible that *G. flavimaculata* is omnivorous and supplements its diet with plant material. More study is needed to determine if this species consumes algae as a primary component of the diet, or if algae is secondarily ingested during foraging for macroinvertebrates.

Submitted by **WILL SELMAN** and **CARL QUALLS**, Department of Biological Sciences, Box 5018, University of Southern Mississippi, Hattiesburg, Mississippi 39401, USA (e-mail: will.selman@usm.edu).

GRAPTEMYS GIBBONSI (Pascagoula Map Turtle). **BASKING AND PARASITE REMOVAL**. The primary physiological role of basking by turtles is presumed to be for thermoregulation (Boyer 1965. Ecology 46:99–118), to increase metabolism and digestion rates (Moll and Legler 1971. Bull. Los Angeles Co. Mus. Nat. Hist. Sci. 11:1–102). However, additional basking hypotheses and secondary roles of basking have been proposed including to aid in vitamin D synthesis (Pritchard and Greenhood 1968. Int. Turtle Tortoise Soc. J. 2:20–25, 34) and to rid turtles of ectoparasites (Cagle 1950. Ecol. Monogr. 20:31–54; Neill and Allen 1954. Ecology 35:581–584; Vogt 1979. Auk 96:608–609). Here we provide evidence to support the hypothesis that basking aids turtles in parasite removal as a secondary role and (to our knowledge) the first documented observation of basking-induced release of a parasite from a turtle while basking.

On 17 May 2007 (1125 h), WS and DS observed a large female *Graptemys gibbonsi* (>20 cm, ca. 1500 g) emerge on a large log-sized snag to bask (Leaf River, Forrest Co., Mississippi). The female emerged facing the observers and a large leech (*Placobdella* sp.) was noted on the anterior left pleural scute of the carapace. At this time, the leech was in an elongated position. After 10 minutes (1135 h), the leech was observed shortening into a ball-shaped posture; it is presumed that this posture was used by the leech for water conservation. After 35 minutes of basking (1200 h), the turtle began to exhibit 'gaping' behavior while basking, evidently reaching a high internal body temperature. Soon after at 1212 h (47 minutes after turtle emergence), the leech terminated the ball-shape and moved slowly toward the left margin of the turtle near the bridge of the shell. At 1214 h (after 49 minutes), the leech removed one end of its body from the margin of the turtle and began to 'search' below toward the log, while the other end was still attached at the margin of the carapace. The leech attached the free end of its body to the log and the attached end on the carapace followed, thus removing itself from the turtle. At 1215 h (after 50 minutes), the leech reentered the water at the edge of the basking log.

During this time, a *G. flavimaculata* female was basking on the same log as the female *G. gibbonsi*. The surface temperature of the *G. flavimaculata* female was being monitored via a carapace mounted temperature sensitive transmitter (AVM Instruments). The carapace temperature of the *G. flavimaculata* female during this observation of the *G. gibbonsi* female was 40–42°C. Therefore, the carapace temperature of the *G. gibbonsi* female was probably comparable to the carapace temperature of the *G. flavimaculata*, and thus, likely hot enough to induce the leech to voluntarily release itself from its host organism. To our knowledge, this is the first documented observation of voluntary parasite release during basking, and supports the secondary hypothesis of basking as a means for parasite removal.

Submitted by **WILL SELMAN, DUSTIN STRONG,** and **CARL QUALLS**, Department of Biological Sciences, Box 5018, University of Southern Mississippi, Hattiesburg, Mississippi 39401, USA (e-mail: will.selman@usm.edu).

GRAPTEMYS GIBBONSI (Pascagoula Map Turtle). **INTERSPECIFIC COMPETITION FOR BASKING SITES**. *Graptemys* gibbonsi is a highly aquatic freshwater turtle that inhabits the Pearl and Pascagoula rivers and tributaries of Mississippi and Louisiana, USA (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institute Press, Washington, D.C. 578 pp.). Very little is known concerning the life history and ecology of *G. gibbonsi*, and previous research within the Pearl and Pascagoula Rivers has focused predominantly on the two federally threatened species (*G. flavimaculata* within the Pascagoula River and *G. oculifera* within the Pearl River) that occur sympatrically with *G. gibbonsi*. These observations of *G. gibbonsi* basking behavior were made within the Pascagoula River system.

On 14 June 2006 (1200 h), on the Chickasawhay River (Greene County, Mississippi), WS observed a male *G. gibbonsi* emerge from the water and position himself above the water's surface on a low-angled, branch-sized snag. After several minutes, a slightly larger *Apalone* sp. approached and climbed onto the submerged portion of the same snag. The *Apalone* remained partially above the surface of the water, but was apparently not in an optimal basking location; it then extended its head forward and proceeded to nudge or bite (unknown due to the observation distance) the posterior of the male *G. gibbonsi*. The *G. gibbonsi* reacted by climbing up the snag. This sequence occurred again until the *G. gibbonsi* moved far enough up the snag to allow the *Apalone* to emerge fully from the water, presumably achieving a more optimal basking site.

On 11 April 2007 (1250 h), WS observed a male *G. gibbonsi*, ca. 9 cm in carapace length, climb vertically 19.5 cm to get to a desired basking location on a low-angled snag (Leaf River, Forrest County, Mississippi). No other turtles occupied the log at this time. This chosen basking location was 1.5–1.8 m from the lowest angle at the air/water interface where most turtles would emerge onto the snag. It could have chosen this "easier" location to emerge and only climb a 10–15° angle rather than the chosen vertical climb. It is unclear why the *G. gibbonsi* male chose this more difficult route to get to a desired basking location. However, it is possible that he took this route to avoid larger turtles that may emerge to bask from the lower angle at the air/water interface.

Submitted by **WILL SELMAN** and **CARL QUALLS**, Department of Biological Sciences, Box 5018, University of Southern Mississippi, Hattiesburg, Mississippi 39401, USA (e-mail: will.selman@usm.edu).

GRAPTEMYS GIBBONSI (Pascagoula Map Turtle). **INTERACTIONS WITH DUCKS.** *Graptemys gibbonsi* is an aquatic turtle that inhabits the Pearl and Pascagoula rivers and tributaries of Mississippi and Louisiana, USA (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institute Press, Washington, D.C. 578 pp.). Very little is known about the life history of *G. gibbonsi* following its description as a species in 1992 (Lovich and McCoy 1992. Ann. Carnegie Mus. 61:293–315). Observations were made on two occasions of interactions between adult female *G. gibbonsi* and Wood Ducks (*Aix sponsa*).

On 11 May 2006 (1500 h), on Oakohay Creek (Covington County, Mississippi), WS observed a basking adult female *G. gibbonsi* on a horizontal log-sized snag, along with a pair of Wood Ducks. The two Wood Ducks were startled by the approaching boat, but the female *G. gibbonsi* was not startled off the log when they flew away. However, the turtle vacated the log ca. 30 seconds

after the ducks flew away, apparently in response to the boat's approach. On 16 April 2007 (1450 h), on the Leaf River (Forrest County, Mississippi) WS observed from shore via spotting scope a female *G. gibbonsi* basking on a large log-sized snag with three *Pseudemys concinna*. A female Wood Duck was also perched above the four turtles on the same log. Upon noticing their observer, the female Wood Duck, and a male Wood Duck (that was previously unnoticed nearby on the water), flew away but none of the turtles were startled by this event. The turtles remained on the log and were only startled once they were approached by boat ca. 5 minutes later. From these observations, it appears that Wood Ducks are not viewed as a potential predator by these turtles and further, do not serve in any 'sentinel' capacity to alert turtles of danger while these turtle species are basking.

Submitted by **WILL SELMAN** and **CARL QUALLS**, Department of Biological Sciences, Box 5018, University of Southern Mississippi, Hattiesburg, Mississippi 39401, USA (e-mail: will.selman@usm.edu).

KINOSTERNON SCORPIOIDES ABAXILLARE (Central Chiapas Mud Turtle). **SIZE, GROWTH, AND REPRODUCTION**. Since its description (Baur, in Stejneger 1925. J. Washington Acad. Sci. 15[20]:462–463) the only published growth or reproductive data for *Kinosternon scorpioides abaxillare* were those of Alvarez del Toro (1983. Los Reptiles de Chiapas. Tercera Edición, Corregida, y Aumentada. Instituto Historia Natural, Los Tuxtlas, Chiapas. 248 pp.), who reported that 6–12 eggs are laid in March or April, and they hatch after three months. The present report is based on 23 specimens trapped between 1700 h 30 April and 0800 h 1 May 1981 (15 in the first two hours) near the Rio Cintalapa bridge on Hwy 190 in Chiapas, Mexico, as well as 52 examined museum specimens of this subspecies (see acknowledgments).

Males did not differ significantly from females in carapace length (CL: males, 122.4 ± 15.7 mm, 88–149, N = 21 versus females, 118.6 ± 14.6 mm, 84–153, N = 36; t = 0.93, P = 0.35) or plastron length (PL: males, 116.1 ± 15.6 mm, 83–143, N = 20 versus females,115.8 ± 14.8 mm, 81–149, N = 36; t = 0.8, P = 0.94), but differed significantly for the ratio PL/CL (males, 0.95 ± 0.02, 0.91–0.99, versus females, 0.98 ± 0.02, 0.93–1.01; t = 3.6, P = 0.0007). Females outnumbered males in the field collection (12:7) and the museum collections (24:14). Body mass (in grams) for the field-collected animals was related to CL (in mm) by the equation $BM = 0.000506CL^{2.727}$ (r = 0.994; P < 0.0001; N = 23), and the equations for males and females were nearly identical. A single neonate (CU 48847) was available, collected 25 June 1971, and measured 29.6 mm CL and 24.1 mm PL.

Although *K. s. abaxillare* was originally diagnosed as lacking an axillary scute, of 66 specimens examined for the trait, 8 had partial medial axillary seams, and 6 had complete axillary seams. In addition, I have observed the absence of axillary scutes in occasional specimens of *K. s. cruentatum* from Veracruz (BCB-SM 7852) and Cozumel (UF 24135, 24138).

The largest immature (no eggs, corpora lutea, or ovarian follicles > 3 mm), field-collected females were 99, 102, 110, 110, 121, and 126 mm CL. The smallest mature females were 124 mm CL (two 9 mm follicles), and 130 mm (one 8 mm follicle). Other mature females were 130 mm CL (follicles, 15, 15, 10, 10 mm), 130 mm CL (9, 9, 8, 8, 8, 8, 8 mm), 131 mm CL (9, 9, 8, 8 mm), and 133 mm CL (8, 8, 8, 7). These data suggest sexual maturity at 120–130 mm CL. Another 132 mm CL female (UIMNH 39373; 27 December 1955) bore 5 partially shelled oviducal eggs (3 crushed, the others 32.3 × 16.5 mm, and 28.75 × 17.5 mm), and follicles of 14, 13, 13, 9, and 8 mm, but counts of corpora lutea were not possible because of preservative effects. These preliminary dissection data suggest that clutch sizes might range from one to five eggs, and that the clutch sizes reported by Alvarez del Toro (*op. cit.*) may be exaggerated. The presence of preovulatory and enlarged follicles in females at the beginning of May suggest that the production of clutches might be possible in May and June, in addition to March and April as suggested by Alvarez del Toro (*op. cit.*). Furthermore, the ovaries of the UIMNH female suggest that eggs could also be laid in January. Whether *K. s. abaxillare* exhibits as long a reproductive season as captive *K. scorpioides* from Honduras (Goode 1994. *In* Murphy and Adler [eds.], Captive Management and Conservation of Amphibians and Reptiles, pp. 275–295. Soc. Study Amphib. Rept., Lawrence, Kansas) or *K. s. cruentatum* on the Yucatan Peninsula (Iverson, unpubl.) remains to be determined. In addition, whether *K. s. abaxillare* also exhibits delayed embryonic development, with hatching synchronized to the onset of the summer rainy season, like other populations of Mexican and Central American *K. scorpioides* (Ewert 1991. *In* Deeming and Ferguson [eds.], Egg Incubation: Its Effect on Embryonic Development in Birds and Reptiles, pp. 173–191. Cambridge Univ. Press, Cambridge, UK), also deserves attention.

Measurements of right abdominal scute annuli were used to estimate previous plastral lengths following the method of Ernst et al. (1973. Herpetologica 29:247–250). Three estimates of PL for age one year were 34.2, 40.9, and 39.3 mm; four estimates for two years were 45.2, 52.1, 62.0, and 66.4 mm; one for three years was 64.2 mm; and one for four years was 70.7 mm. A crude extrapolation of those data suggests that 8–10 years would be required to approach maturity at 120 mm PL (ca. 122 mm CL).

I thank T. Leithauser, R. Magill, P. A. Meylan, P. Moler, and C. R. Smith for field assistance, and the American Museum of Natural History (AMNH; D. Frost, C. W. Myers, R. G. Zweifel), the University of Colorado Museum (CU; T. P. Maslin, H. M. Smith), the University of Kansas Museum of Natural History (KU; J. T. Collins, W. E. Duellman), the Museum of Comparative Zoology at Harvard University (MCZ; J. Rosado, the late E. E. Williams), the Strecker Museum (BCB-SM; B. Brown), the Texas Cooperative Wildlife Collection (TCWC; J. R. Dixon), the University of Arizona collection (UAZ; the late C. W. Lowe), the University of Florida-Florida State Museum (UF; the late W. Auffenberg, P. A. Meylan), the University of Illinois Museum of Natural History (UIMNH; D. Hoffmeister, D. Smith), the University of Michigan Museum of Zoology (UMMZ; A. G. Kluge, R. Nussbaum, the late D. W. Tinkle), the United States Natural History Museum (USNM; R. Crombie, R. W. McDiarmid, R. Reynolds, G. R. Zug), and the University of Utah (UU; J. F. Berry, J. M. Legler) for the loan of specimens. La Dirección General de la Fauna Silvestre de México provided permits for the field work. Treatment of all animals was in accordance with the ethical principles outlined in the SSAR Guidelines for Use of Live Amphibians and Reptiles in Field Research. Support for the project was provided by Earlham

College, and the Joseph Moore Museum of Natural History.

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). **DIET**. *Kinosternon subrubrum* is an ubiquitous turtle found in wetlands throughout the eastern U.S. Food items taken by this turtle were listed in Ernst et al. (1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, D.C.), and include invertebrates, vertebrates, and plant material. On 27 July 2007, we discovered the carcass of an adult *K. subrubrum* on the substrate of a large drying beaver pond in Tuskegee National Forest, Macon County, Alabama (UTM 16S 0627179N 3588804E). The turtle measured 97 mm in carapace length and 82 mm in plastron length, and is believed to be a male due to its deep posterior plastral notch (AUMO 37608). Upon dissection, the specimen was found to contain 190 seeds of the aquatic plant *Nuphar luteum* (spatterdock or yellow pond-lily) and one chelicera of a crayfish (*Cambarus* sp.). This represents the first record of *K. subrubrum* feeding on the seeds of *N. luteum.* The seeds appeared to be ripe and at a later stage of development than seeds found on the *N. luteum* at the time of collection, suggesting that the turtle may have been foraging on the seeds in the mud on the bottom of the pond. Finally, it is possible that this species may play a role in the seed dispersal of this plant, although seed viability experiments would need to be performed to confirm this.

We thank C. Guyer for comments on this note. This observation was made while conducting research funded by NIH grant R01-A149724 under ADCNR Permit 4268.

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). **CARRION FEEDING.** *Terrapene carolina triunguis* is common throughout Arkansas and is reported to have a broad-based omnivorous diet (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas, Univ. Arkansas Press, Fayetteville, 421 pp.). Carrion is commonly reported in the diet of box turtles (Dodd 2001. North American Box Turtles: A Natural History, Univ. of Oklahoma Press, Norman, 231 pp.). Dead birds, including ducks (*Anas* spp.) and Green Herons (*Butorides striatus*) have been recorded in the diet of *T. carolina* (Ernst et al. 1994. Turtles of the United States and Canada, Smithsonian Institution Press, Washington, 578 pp.). The literature appears to lack mention of smaller birds, such as songbirds (passerines) being consumed as carrion. Here we report the consumption of a Brown-headed Cowbird (*Molothrus ater*) as carrion by a *T. c. triunguis*.

As part of a study estimating scavenging rates of avian carcasses, we distributed eight female Brown-headed Cowbird carcasses throughout an open field in Greene Co., Arkansas on 10 September 2007. On 13 September 2007 at 0735 h, one of us (IG) observed a male *T. c. triunguis* (113.6 mm CL, 87.5 mm CW, 308 g) feeding on one of the cowbird carcasses (UTM 15N 0701128, 3975567). The turtle was measured, sexed, and then released. Because small birds inevitably share habitat with box turtles, their consumption as carrion by the turtles is not unexpected and may occur fairly frequently.

TRACHEMYS GAIGEAE GAIGEAE (Big Bend Slider). **KYPHOSIS.** The term kyphosis has been used, often incorrectly, to describe a variety of spinal deformities seen in turtles, ranging from true kyphosis to lordosis (Rhodin et al. 1984. British J. Herpetol. 6:369–373). During studies of *Trachemys g. gaigeae* in the Rio Grande Valley of Socorro and Sierra counties, New Mexico in 1994–1998, we captured a small adult male that was distinctly kyphotic or possibly kyphoscoliotic (*sensu* Rhodin et al., *op. cit.*). The turtle (Fig. 1) was captured in May 1998 in Elephant Butte Reservoir near Nogal Canyon, Sierra Co. and had the following measurements: straight-line carapace length at midline (CL) = 135 mm; straight-line plastron length at midline (PL) = 123.5 mm; maximal shell width = 111 mm; maximal shell height (at hump) = 61.5 mm; mass = 346 g. The hump was centered slightly to the right of the carapace midline at the second vertebral scute, suggesting kyphoscoliosis. All five vertebral scutes (V1–V5) were irregular in shape and asymmetrical. No melanistic disruption of the shell and skin color pattern, a common feature of older and larger male *T. g. gaigeae*, was evident. The slider appeared healthy when captured, but later died in captivity.

Four other specimens (all adults that were marked and released) were examined from our study area that exhibited varying degrees of kyphosis or kyphoscoliosis, although none as pronounced as the illustrated example. These included: 1) a female (258.5 mm CL; 238 mm PL) with a slight, localized hump to the right of the midline of V2 and V3; 2) a female (245 mm CL; 233 mm PL) with a slight, localized hump to the left of the midline of V2 and V3; 3) a female (268 mm CL, 239 mm PL) with a highly domed carapace

FIG. 1. Kyphotic male *Trachemys g. gaigeae* from Sierra Co., New Mexico.

centered to the left of the midline; and 4) a male (114 mm CL; 105 mm PL) with a hump between V1 and V2; spine laterally curved at hump; scutes V1–V5 were deformed.

Only 5 of the 235 (2.1%) adult and subadult specimens examined in our study exhibited noticeable kyphosis or kyphoscoliosis, and only one (0.4%) was markedly abnormal. We observed no spinal deformities in any hatchlings (N = 123) obtained from gravid females captured in the study area (Stuart and Painter 2006. Herpetol. Rev. 37:79).

Within the genus, kyphosis or related spinal deformities have been reported in *T. scripta scripta* (Carr 1952. Handbook of Turtles: The Turtles of the United States, Canada, and Baja California. Cornell Univ. Press, Ithaca, New York), *T. s. elegans* (Tucker et al. 2007. Herpetol. Rev. 38:337–338), *T. s. troostii* (Cagle 1950. Ecol. Monog. 20:31–54), and *T. yaquia* (Plymale et al. 1978. Southwest. Nat. 23:457–462). Tucker et al. (*op. cit.*) found kyphosis in only 0.06% of all *T. s. elegans* (N = 21,786) they captured in Illinois but noted that higher rates of occurrence (< 2.6%) have been reported in other turtle species based on much smaller sample sizes. Our report is the first for spinal deformities in *T. gaigeae* and suggests that its occurrence is also uncommon in this species.

We thank C. Travis Darwin for help in the field.

SQUAMATA — LIZARDS

ABRONIA TAENIATA (Bromeliad Arboreal Alligator Lizard). **MICROHABITAT.** Lizards of the genus *Abronia* (Anguidae) display both morphology and behavior specialized for arboreality (Campbell and Frost 1993. Bull. Am. Mus. Nat. Hist. 216:1–121). The genus also appears to be among the most endangered of Neotropical squamate lineages, and several species are known from only one or a few specimens (Campbell and Frost, *op. cit.*). In addition, species of *Abronia* are secretive (Formanowicz et al. 1990. Biotropica 22:391–396), and probably exhibit naturally low densities, though detailed information on population size is difficult to obtain in their arboreal habitats. Consequently, observations of *Abronia* are rare, and few reports describe activity in terrestrial environments (Martin 1955. Copeia 1955:173–180; Campbell and Frost, *op. cit.*). *Abronia taeniata* is a relatively widespread Mexican species that occurs in the pine-oak forests of the Sierra Madre Oriental between 1000–3000 m (Martin 1958. Misc. Publ. Mus. Zool. Univ. Michigan 101:1–102). Terrestrial habitat use in this taxon has been infrequently reported, with little information available on associated behavior (Martin 1955, *op. cit.*). Here, we provide two additional observations of terrestrial activity in this species from the state of Hidalgo.

At 1545 h on 1 July 2006, BPS, ELMV, and NI found an adult female *A. taeniata* (83.9 mm SVL, 116.5 mm tail, 10.7 g) in the crevice of a large limestone boulder (20.8778°N, 99.2299°W, datum: WGS84; elev. 2464 m) under pine (*P. greggii/P. patula*)-oak (*Q. crassipes*) forest canopy near the community of La Manzana, in Parque Nacional Los Mármoles (PNLM). The observation was made following strong morning rains. On our approach, the *A. taeniata* retreated into the boulder, but we captured it at 1645 h after it reappeared at the edge of the same crevice. The nearest tree (a mature pine, probably *P. greggii)* was ca. 1.5 m away.

Elsewhere in the range of *A. taeniata*, the species has been collected in trees (Martin 1958, *op. cit.*). Other species of *Abronia* have been collected on tree trunks, and in epiphytic bromeliads and mosses (Campbell and Frost, *op. cit.*). In the Los Mármoles region, however, mature trees support few large epiphytes (BPS, pers. observ.), so *A. taeniata* may use terrestrial refugia in this area with greater frequency, at least during inclement weather. The specimen (BPS-CIB 24) was deposited in the vertebrate collections of the Centro de Investigaciones Biológicas (CIB) at the Universidad Autónoma del Estado de Hidalgo.

At 1030 h on 29 March 2007, IECS also found an adult female *A. taeniata* (106.8 mm SVL, 143.0 mm tail, 19.0 g) on leaf litter in a pine (*P. rudis)*-oak (*Q. rugosa*) forest at Campamento Conejo in Parque Nacional El Chico (20.1877°N, 98.7097°W, datum: WGS84; elev. 2915 m). The lizard was found in a patch of forest floor illuminated by morning sunlight; the nearest trees were 2–3 m away. IECS observed it for ca. 15 min, then captured it for deposition into the CIB vertebrate collection (specimen: ARP-00109).

We thank A. Leyte Manrique for logistical assistance. Jonathan A. Campbell (University of Texas, Arlington) confirmed the PNLM record as *A. taeniata*. We thank SEMARNAT and SRE (Government of Mexico) for providing collecting permits, and the Municipality of Zimapán and the Bienes Comunales of La Encarnación for providing additional logistic support. AMEIVA EXSUL (Puerto Rican Ground Lizard). **DIET**. *Ameiva exul* has a diverse diet that includes invertebrates (earthworms, snails, insects, crabs), vertebrates (frogs, lizards), vegetable matter (banana, apple, cactus fruits), dog food, and even certain types of garbage (Joglar [ed.] 2005. Biodiversidad de Puerto Rico–Vertebrados Terrestres y Ecosistemas. Editorial del Instituto de Cultura Puertorriqueña, San Juan. 563 pp.; Lewis 1989. J. Herpetol. 23:164–170; Rivero. 1998. Los Anfibios y Reptiles de Puerto Rico. Editorial de la Universidad de Puerto Rico, San Juan. 510 pp.). Here, we add observations of several unreported food items to its already broad diet.

At 1247 h on 3 November 2005, we observed an adult *A. exsul* (ca. 13 cm) capture and eat an adult male of the Puerto Rico ground tarantula spider (*Cyrthopholis portoricae*; ca. 30 mm cephalotho-

FIG. 1. Common Ground Lizard (*Ameiva exsul*) ingesting a Puerto Rico Ground Tarantula (*Cyrthopholis portoricae*).

rax–abdominal length)) at Gurabo Abajo, Juncos, Puerto Rico (18.2519°N, 65.8964°W; datum: WGS84; elev. 171 m). The lizard, which located the male tarantula from a distance of ca. 3 m, rushed the spider, grabbed it (Fig. 1), and broke it into pieces by striking it on the substrate before eating it. Additional photos of the episode were deposited in the collection at the University of Puerto Rico-Humacao (UPR-H -Ameiva 1,2,3 – 2007).

During February 2007 (dry season), RAPR twice observed a female *A. exsul* (ca. 15 cm) eating insect larvae on drying dog feces at Bairoa Park, Caguas (18.2594°N, 66.0439°W; elev. 82 m). This lizard also ingested 3–4 mm fragments of fecal material that broke off of the fecal bolus.

On 15 September 2007, also in Caguas (18.2353°N, 66.0278°W; elev. 79 m), RAPR observed a Greater Antillean Grackle (*Quiscalus niger*) eating the crust and the insides of a piece of a recently discarded cheese pie. This attracted an adult (ca. 13 cm) *A. exsul* that came to investigate, which induced the grackle to leave. The lizard began eating the coagulated melted cheese almost immediately. A little later, a larger (ca. 15 cm) *A. exsul* supplanted the first, and after examining the remains, also consumed cheese. Additionally, AMO has often observed *A. exsul* in Juncos consume discarded human food as cooked beans, boiled rice, and pieces of boiled squash.

Our observations represent the first report of predation on tarantula spiders and the ingestion of cheese and fecal material by *A. exsul*. Tarantulas such as *Cyrthopholis* may be atypical prey for diurnal lizards. Nevertheless, during the breeding season the males emerge from their holes and start wander in search of females even during light day hours (Torres and Pérez–Rivera 1976. Science-Ciencia 3/4:104–108). Ingestion of feces may also be atypical. Drought reducing the typical prey base for *Ameiva* may explain this rare behavior. Our observations may support the notion that *A. exsul* is and opportunistic generalist, but the possibility also remains that great variation in food selection by individuals in this lizard may exist.

Submitted by **RAUL A. PEREZ–RIVERA** and **ALBERTO MOLINA-OPIO**, Department of Biology, University of Puerto Rico-Humacao, CUH Station, Humacao, Puerto Rico 00791 (e-mail [RAPR]: raperezrivera@yahoo.com).

ANOLIS UNIFORMIS (Lesser Scaly Anole). **DIET.** *Anolis uniformis* is a small lizard widely distributed in wet tropical rain forests from southern Tamaulipas, México through northern Guatemala and Belize to northern Honduras. It occurs in forest understory from near sea level to about 900 m (Campbell 1998. Amphibians and Reptiles of Nothern Guatemala, the Yucatán, and Belize. University of Oklahoma Press, Norman. 380 pp.; Campbell et al. 1989. Biotropica 21:237–243; Lee 1996. The Amphibians and Reptiles of the Yucatan Peninsula. Cornell University Press. Ithaca, New York. 500 pp.). The most observable lizard at Los Tuxtlas tropical rain forest, Veracruz, México, *A. uniformis* is thought to be a diurnal insectivore across its geographic range (Duellman 1963. Univ. Kansas Publ. Mus. Nat. Hist. 15:205–249; Villarreal 1997. *In* González et al. [eds.], Historia Natural de los Tuxtlas. Universidad Nacional Autónoma de México. 647 pp.; Villarreal and Heras 1997. *In* González et al., *op. cit.*). Here we report predation by *A. uniformis* on an anuran.

At 2315 h on 3 September 2003 during a nocturnal herpetofaunal survey, we observed a young *A. uniformis* male (29 mm SVL) swallowing a very small (ca. 9 mm SVL) leaf litter frog (*Craugastor* sp.). The event occurred on a leaf of a medium-sized plant in a small bamboo and tropical rain forest remnant in the Los Tuxtlas region, Veracruz, México (18.6072°N, 95.1437°W, datum: WGS84; elev. 650 m). The anole was collected and deposited in Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México (CNAR IBH 21138).

From September 2006 to July 2007, we also collected and dissected 30 *A. uniformis* adults at the Laguna Escondida rainforest remnant at Los Tuxtlas region (18.5909°N, 95.0883°W; elev. 150 m) as a part of a parasitological study. Examination of stomach and intestinal contents revealed only arthropod remains, mostly terrestrial and flying insects (flying Diptera, Hymenoptera, Hemiptera; terrestrial Orthoptera) and a few spiders. We found no amphibian remains in this sample.

Previous diet records for *Anolis uniformis* (Stuart 1948. Misc. Publ. Mus. Zool. Univ. Michigan 69:1–109; Villarreal, *op. cit.*; Villarreal and Heras, *op. cit.*) indicate that it preys on insects and litter-dwelling invertebrates, especially soft-bodied arthropods. Our 2003 observation indicates that *A. uniformis* can prey on small amphibians and that it may sometimes feed at night

We thank F. Bertoni, M. Márquez, R. Paredes, H. Reyes, and M. Sánchez for assistance in the field.

Submitted by **ELISA CABRERA GUZMÁN** and **VÍCTOR HUGO REYNOSO,** Colección Nacional de Anfibios y Reptiles. Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Circuito exterior, Ciudad Universitaria, México D.F. C.P. 04510; e-mail: anfisbenido@yahoo.com.

ASPIDOSCELIS VELOX (Plateau Striped Whiptail). **PREDATOR EVASION**. Successful attempts form the basis of most predation reports in the herpetological literature. In contrast, failed attempts are rarely reported even though they are essential to understanding of behavior, natural history, and selection pressures of predators and their prey. Here I report an observation of *Aspidoscelis velox* successfully avoiding a predation attempt by a

Long-tailed Weasel (*Mustela frenata*) in southeastern Utah.

At 1051 h on 19 August 2007, in the valley of Indian Creek, San Juan Co., Utah, USA (38.0523°N, 109.5587°W, datum: WGS84; elev. 1697 m), I observed a *M. frenata* moving from an open area of compacted sand to the cover of a Greasewood (*Sarcobatus vermiculatus*) shrub, ca. 40 m W of the intermittent stream channel of Indian Creek. Air temperature was ca. 27°C and cloud cover was 60%. Vegetation was dominated by Big Sagebrush (*Artemisia tridentata*), Greasewood, and Four–wing Saltbush (*Atriplex canescens*). I observed the weasel through 10× binoculars from a distance of ca. 3 m. The weasel seemed aware of my presence as its gaze was fixed in my direction. After ca. 1 min of observation, the weasel darted from the shrub in pursuit of an adult (ca. 7 cm SVL) *A. velox* that I had not previously noticed. The lizard maneuvered in a series of rapid zigzag movements up–slope and away from where the weasel had appeared, making at least four abrupt (ca. 90°) turns over a distance of ca. 4 m. The weasel seemed to follow closely, tracing each abrupt turn of the lizard, but the speed of the pursuit made it impossible to ascertain from my position whether the weasel was gaining on the lizard or the lizard was gaining distance from the weasel. The weasel gave up chase after ca. 4 m and returned rapidly to the shrub from which it had emerged, where it apparently entered a burrow and disappeared from sight. As the weasel gave up the chase, the lizard crested a small rise in the slope, leaving my field of view. Based on the recording times of photographs taken during the chase, the chase lasted ca. 26 sec.

Because the weasel was aware of my presence prior to chasing the lizard it may have been motivated to terminate the chase earlier than it would have otherwise. However, Long-tailed Weasels have been reported to continue apparently normal foraging behavior even in front of large groups of people (e.g., Hamilton 1933. Am. Midl. Nat. 14:289–344). Long-tailed Weasels are regarded as generalist predators even though they eat primarily small rodents, and only rarely take lizards (Sheffield and Thomas 1997. Mamm. Species 570:1–9). Predation attempts, successful or otherwise, by *M. frenata* on *A. velox* have not been previously reported. Whiptail lizards are known for their speed and evasive abilities, and being notoriously difficult for humans to capture is the origin for the species name "*velox*" (Springer 1928. Copeia 169:100–104; Stuart 1998. Cat. Am. Amphib. Rept. 656:1–6). This observation suggests that the rapid zigzag escape strategy of *A. velox* is effective in avoiding capture by other mammalian predators as well.

Submitted by **RYAN P. O'DONNELL**, Department of Biology and the Ecology Center, 5305 Old Main Hill, Utah State University, Logan, Utah 84322–5305, USA; e-mail: Ryan@biology.usu.edu.

COLEODACTYLUS NATALENSIS (NCN). **CLUTCH SIZE; HATCHLING SIZE.** *Coleodactylus natalensis* is a small lizard endemic to the Atlantic Forest of Rio Grande do Norte, Brazil (Freire 1999. Bol. Mus. Nac. 399:1–14). Clutch size is not known, but its geographically proximate congener, *C. meridionalis*, has a one-egg clutch (Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras. de Ciênc. Rio de Janeiro, Brazil. 161 pp.). Here, we provide an observation of clutch size and hatchling size in *C. natalensis*.

At 1630 on 24 January 2006, PAGS collected two eggs of *C. natalensis* ca. 1 m apart among leaf litter in a 30-cm deep cavity in a large rock (ca. 1 m^2) at the Estação Experimental Rommel Mesquita de Faria (Mata do Jiquí; 5.9305°S, 35.1814°W; datum: WGS84; elev. 40 m), an Atlantic Forest fragment on an EMPARN (Empresa de Pesquisas Agropecuárias do Rio Grande do Norte) farm of 79 ha in the of municipality Parnamirim. These data and field observations of females carrying one egg (CMCAL, pers. obs.) indicates that this species likely has a fixed clutch size of a single egg.

The eggs were placed in a terrarium (20 cm × 12 cm × 20 cm) with a substrate of sand and leaf-litter, and maintained at Laboratório de Herpetologia, in the Departamento de Botânica, Ecologia e Zoologia in Universidade Federal do Rio Grande do Norte) at an ambient temperature averaging about 25°C, but which varied between 24°C and 32°C over the incubation period. On 6 March 2006 (41 days after collection), one juvenile emerged. Measurements were SVL: 11 mm; tail length: 0.8 mm; foreleg length: 3.1 mm; fourth finger: 0.4 mm; hindleg length: 3.6 mm; fourth toe: 0.7 mm; head length: 2.9 mm; head width: 2.0 mm; jaw length: 1.6 mm; head height: 1.1 mm; body width: 2.2 mm; pelvis width; 1.3 mm; axilla–groin length: 4.4 mm; and mass: 0.024 g. This is the first record of hatchling size in *C. natalensis*.

The specimen (CHBEZ 1504) was deposited in the Herpetological Collection of Universidade Federal do Rio Grande do Norte (CHBEZ), municipality of Natal. We thank two anonymous reviewers for suggestions on the manuscript. Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) provided research grants to LBR (process 141993/2006-5) and to PAGS (process 107762/2006-4).

CYCLURA CYCHLURA CYCHLURA (Andros Iguana). **ATTEMPED PREDATION.** Shifts in prey size may reflect several processes including limitations on gape (Shine and Sun 2003. Funct. Ecol. 17:340–348). Alternatively, rather than the ability to physically ingest prey, limitations may reflect a predator's ability to capture, kill, or digest prey of different sizes. Few field accounts exist demonstrating a snake's ability to dispatch but not ingest prey (but see Sabo and Ku 2004. Herpetol. Rev. 35:396–397). The few reports of failed predation attempts may reflect a combination of the inability to record them without direct observation and bias against reporting unsuccessful predation events even though such events can inform aspects of species-specific predation be-

havior unavailable elsewhere. Here we report three failed predation attempts by snakes on hatchling *Cyclura cychlura cychlura* from two island localities over an eight-day period in September 2003.

In coordination with a hatchling dispersal study of the Andros Iguana, we affixed 2.7 g radio-transmitters (model PD-2, Holohil Systems, Ltd., Ontario, Canada) to 41 hatchling iguanas (Knapp and Owens 2005. Herpetol. Rev. 36:264–266) on Sandy and Mangrove Cays of Andros Island, Bahamas (see Knapp and Owens 2004. Caribb. J. Sci 40:265–270 for site descriptions). We attempted to locate telemetered hatchlings daily after release at their respective nests. On 3 September 2003 (20 days after release), we found a dead hatchling *C. c. cychlura* (102 mm SVL, 45 g) on the limestone substrate of Mangrove Cay. The head of this hatchling was severely compressed with blood seeping from the mouth and tympanum, while the head and thorax were coated with shiny clear and brown residue. The residue extended down half the body and stopped ca. 10 mm anterior to the transmitter, which was attached on the dorsal side of the pelvic girdle. On 4 and 11 September 2003 (3 days after release for each hatchling), we found dead hatchling iguanas (98 mm SVL, 43 g; 93 mm SVL, 38 g) on the limestone substrate of Sandy Cay. The skull of each hatchling was similarly compressed with blood seeping from the mouth and tympanum. These hatchlings differed from the first observation in that only the head was coated with shiny clear and brown residue and stopped at the pectoral girdle. These observations are similar to a failed predation attempt on *Sceloporus occidentalis* (Sabo and Ku, *op. cit.*) and led us to conclude that the hatchlings had been captured, partially swallowed but regurgitated by a predator. Only two snakes (*Alsophis vudii* and *Epicrates striatus*) occurring at our study sites have been confirmed to be capable of ingesting hatchling *C. c. cychlura* iguanas. Indeed, we recorded 18 *A. vudii* individuals consuming 19 *C. c. cychlura* hatchlings and six *E. striatus* individuals consuming nine hatchlings. We infer that the failed predation attempts were attributable to *A. vudii* based on the fresh, wet residue on the carcasses, which were discovered during the day. Additionally, based on observations of predator-prey interactions for both species of snakes using radio telemetry, the open locations of the carcass discoveries are indicative of typical kill sites for the diurnal *Alsophis* rather than the nocturnal *Epicrates*. Snakes are known to feed selectively, and hence need to discriminate between objects that are or are not acceptable as food (Shine and Sun 2003, *op. cit.*). Our observations are significant because they indicate that potentially gape–limited snakes may be successful in capturing and subjugating prey but can fail in their ingestion attempts. Sabo and Ku (*op. cit.*) concluded that a failed predation attempt of a gravid *S. occidentalis* was the direct result of the girth of the body cavity caused by the internal egg mass. In our case, the first failed predation event where the clear and brown residue extended to within 10 mm of the pelvic transmitter could be attributable to the increased girth caused by the transmitter. However, it appeared as if the ingestion process was aborted anterior to the pectoral girdle in the latter two observations indicating that the snakes were able to dispatch but not ingest their prey items. We suspect that failed predation events may be more common than expected and that these events can provide interesting hypotheses for testing evolutionary predator-prey relationships.

We thank the Bahamas Department of Agriculture for permission to conduct our research and permits. The John G. Shedd Aquarium and a grant from the Association of Zoos and Aquariums (AZA) Conservation Endowment Fund supported our research.

ECPLEOPUS GAUDICHAUDII (NCN). **REPRODUCTION.** *Ecpleopus gaudichaudii*, a poorly known gymnophtalmid lizard, is thought to be endemic to the Atlantic Rainforest of southeastern Brazil (Peters et al. 1986. U.S. Nat. Mus. Bull. 297:1–293). Data on clutch size and reproductive behavior is limited to one observation of two individuals (Uzzell 1969. Postilla 135:1–23). Herein, we report data on seven gravid females collected in Minas Gerais, southeastern Brazil.

All specimens are deposited in the herpetological collection of the Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil. All seven females, collected in arthropod and/or herpetofauna pitfall traps, contained one developed egg averaging 7.0 ± 0.3 mm SD (range: 7.5–6.7 mm). UFMG 987 (36.6 mm SVL) was collected in an area of secondary forest of a small urban park, the Estação Ecológica da UFMG (19.92°S, 43.93°W; elev. 850 m) in the interval 24–30 October 2000. UFMG 1659, 1663, 1661, and 1660 (respectively 34.9, 34.7, 35.2, and 35.3 mm SVL) were collected in primary forest of a large Atlantic Rainforest reserve, the Parque Estadual do Rio Doce (19.80°S, 42.63°W; elev. 230–515 m) in the interval 1–10 September 2001. UFMG 1094 (38.4 mm SVL) was collected in primary forest of another Atlantic Rainforest reserve, the Reserva do Patrimônio Natural Feliciano Miguel Abdala (19.83°S, 41.83°W; elev. 340–680 m) in the interval 22 December 2000–16 January 2001, whereas UFMG 1095 (37.1 mm SVL) was collected in the same locality, but lacks a collection date. These observations agree with the previous observation (Uzzell 1969, *op. cit.*) that *E. gaudichaudii* clutch size is typically one egg.

PERINI**, Laboratório de Biodiversidade Molecular, Departamento de Genética, Instituto de Biologia, Universidade Federal do Rio de Janeiro, CP 68011, Rio de Janeiro, RJ, CEP 21941–590, Brazil (e-mail: faperini@yahoo.com.br); and **MARIELLA BUTTI**, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, CP 486, Belo Horizonte, MG, CEP 31270–901, Brazil (e-mail: maributti@uol.com.br).

ELGARIA COERULEA (Northern Alligator Lizard). **JUVENILE GROWTH**. Rutherford (2004. Can. J. Zool. 82:817-822) provided the only juvenile growth data for *Elgaria coerulea*, but those data were based on individuals from the Creston Valley, British Columbia, located toward the northern end of the species range

(Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 560 pp.). Hence, we provide an observation of juvenile growth in *E. coerulea* from west-central Washington State.

We recorded these observations along the south edge of a second-growth Douglas-fir (*Pseudotsuga menziesii*) stand in a rural neighborhood < 0.15 km from Puget Sound near Olympia, Washington (47°06'59"N, 122°56'08"W, WGS 84; elev. 37 m). All measurements were made with a 15-cm ruler to the nearest 0.5 mm; and masses were obtained with a top-loading Ohaus 1320 field scale with 0.01 g accuracy.

While cleaning yard debris at 2010 h on 29 May 2007, CBH captured a juvenile female *E. coerulea* (49.0 mm SVL, 65.0 mm tail [unbroken], 1.70 g) beneath a discarded painting tarp exposed daily to midday and afternoon sun. Based on having recaptured *E. coerulea* under similar objects, we opted not to remove the tarp, marked the animal with a single toe clip, and released it at the capture point. MPH subsequently recaptured this animal at the same location three times over the next 65 days. On 15 June, it was 52.5 mm SVL (75 mm tail, 2.26 g); on 2 July, it measured 55 mm SVL (82.5 mm tail, 2.50 g); and on 8 August, it was 60 mm (92 mm tail [still unbroken], 3.55 g). These data reveal mean growth rates of 0.21 mm/dy and 0.59 mm/day for the body and tail in the 1st interval; 0.15 mm/dy and 0.44 mm/day in the 2nd interval; and 0.16 mm/dy and 0.24 mm/dy in the 3rd interval. Mass increased 0.04 g/dy in the 1st interval, declined to 0.01 g/dy in the 2nd interval, but increased again to 0.03 g/dy in the 3rd interval.

Based on the data of Rutherford (*op. cit.*) and the fact that the smallest *E. coerulea* observed locally (28–32 mm SVL) have always been found in later summer and fall (MPH, unpubl. data), the animal we captured belongs to the 2006 cohort. Based on the growth curve of Rutherford (*op. cit.*), the growth of this juvenile seems slightly faster than that of juveniles from the Canadian Okanogan; no animal that Rutherford captured had attained 60 mm by their second winter (see her Figure 2), and after our last recapture, we expect to have at least 40 days of higher-growth-rate temperature conditions in our summer season. One further point merits comment. Growth rate of the tail declining nearly three-fold relative to the roughly constant body growth rate as mass increased indicates that substantial allocation to tail growth occurs early, asymmetry that deserves exploration.

Work was done under a Washington Department of Fish and Wildlife programmatic handling permit under which MPH was a permitee. This is contribution No. 16 of the Forests and Fish Section of the Washington Department of Fish and Wildlife Habitat Program Science Division.

EUMECES ELEGANS (Elegant Skink). **PREDATION**. *Eumeces elegans* occurs in eastern China, Taiwan, and the Diaoyutai (=Senkaku) Archipelago (Hikida 1993. Japan. J. Herpetol. 15:1–21). In Taiwan, it inhabits primarily open mountainous areas and

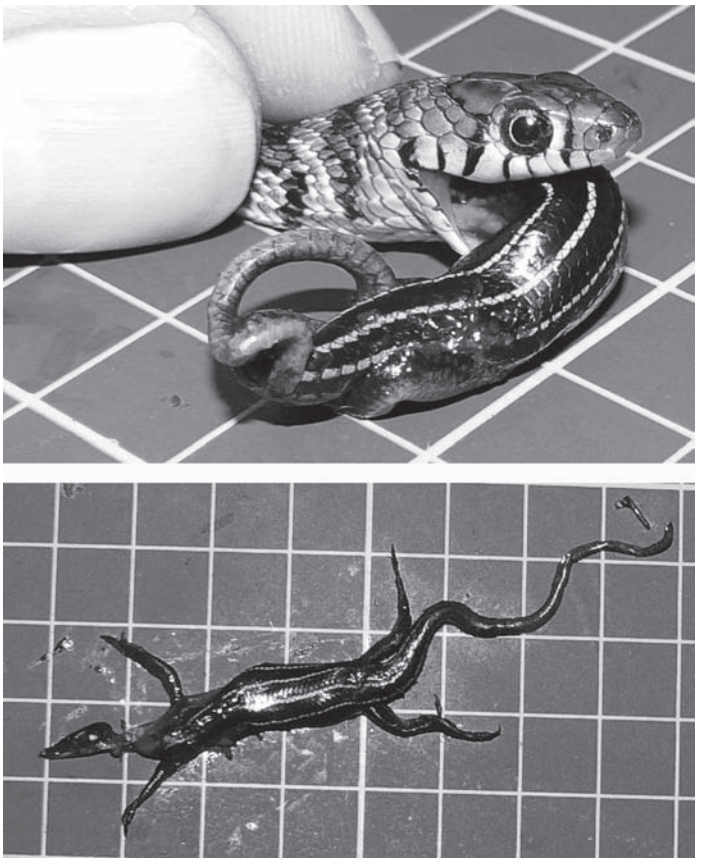

FIG. 1. The *Amphiesma stolatum* in the process of regurgitating the *Eumeces elegans* (top), and the prey item after it has been regurgitated (bottom). Note the partly digested head of the prey in the bottom image.

areas disturbed by human activities below 2500 m (Lue et al. 2002. The Transition World—Guidebook of Amphibians and Reptiles of Taiwan. SWAN, Taipei. 350 pp. [in Chinese]; Pope 1929. Bull. Amer. Mus. Nat. Hist. 58:335–487; Shang and Lin. 2001. Natural Portraits of Lizards of Taiwan. Big Trees Publishers, Taipei. 174 pp. [in Chinese]).

On 14 September 2007, a juvenile male Striped Keelback (*Amphiesma stolatum*) (293 mm SVL, 100 mm tail, 9.3 g post–regurgitation mass) was collected from a drift fence funnel trap set in a Betelnut Palm (*Areca catechu*) plantation in Santzepu, Sheishan District, Chiayi County (23.4267°N, 120.4856°E; datum: WGS84; elev. 85 m). Habitat consisted of *A. catechu*, *Alocasia odora*, *Bidens pilosa* var. *radiata*, *Ipomoea cairica*, *Mikania micrantha*, and *Panicum maximum*; canopy cover, created by the crowns of *A. catechu*, was 25%. The *A. stolatum* had an enlarged mid-body, and after gentle palpation, the snake regurgitated a juvenile *E. elegans* (Fig. 1) with a partly digested head (45 mm SVL, 59 mm tail, 1.4 g). After being scale-clipped for future identification, the snake was released in the area where it was collected.

Little is known about the feeding habits of *A. stolatum*, but the following prey types have been recorded: insects (Acrididae), tadpoles, toads, frogs, fish (Lee and Lue 1996. Biol. Bull. Nat. Taiwan Normal Univ. 31:119–121 [in Chinese]), earthworms, geckoes, lizards, and scorpions (Das 2002. A Photographic Guide to Snakes and Other Reptiles of India. New Holland Publishers [UK] Ltd., London. 144 pp.). Prey size of the skink reported here, at

15% of predator mass, is typical for a colubrid (Greene 1997. Snakes: The Evolution of Mystery in Nature. University of California Press, Berkeley. 351 pp.). This is the first description of *E. elegans* as prey of *A. stolatum*.

FURCIFER LABORDI (Labord's Chameleon). **REPRODUCTION.** Though nesting behavior in *Chamaeleo chamaeleon* is relatively well-studied in Spain (Blázquez et al. 2000. Herpetol. J. 10:91–94), nest excavation behavior in chameleons of Madagascar remains undescribed. Additionally, such behavior in nature may differ from that described for captives or under semi-natural environments (e.g., Bourgat 1968. Bull. Soc. Zool. France 93:355–356.; Ferguson et al. 2004. The Panther Chameleon: Color Variation, Natural History, Conservation, and Captive Management. Krieger Publishing Co., Malabar, Florida. 118 pp.). Here, we describe clutch size and nest excavation behavior in a chameleon from Madagascar, *Furcifer labordi*. To our knowledge, no other published field observations of nesting in this species exist.

On 03 February 2004, we observed nest excavation and egg deposition by an adult female *F. labordi* (77.2 mm SVL) at Ranobe forest (23.0250°S, 43.6100°E, datum: WGS84; elev. 17 m), ca. 30 km N of the provincial capital of Toliara (Tuléar), southwestern Madagascar. We located this female ca. 2 h before dusk at 1654 h, after she had already excavated a burrow deep enough to have submerged ca. 10 cm of her total body length below the substrate. The female dug the entrance burrow in the sand substrate at a roughly 45° angle. For the next 4 h and 18 min, she remained underground. In *Chamaeleo chamaeleon*, and in captive chameleons from Madagascar, females use only one burrow during nest excavation (Blázquez et al., *op. cit.*; KBK, pers. obs.). However, the female of this species deposited eggs without exiting the same burrow, and instead, excavated upwards at an angle almost perpendicular to the entry burrow. She emerged from the opposite end at 2112 h, filling in the burrow as she exited. By 2137 h, she had completely exited and remained motionless for the next 18 min. By 2155 h, she began to crawl toward the burrow entrance, and began covering the partially collapsed entrance. She completed filling the entrance by 2230 h, after which she climbed nearby vegetation to roost. We estimate that nesting behavior in this individual lasted at least 6 h given that she had begun excavation before we arrived, much shorter than that described in *C. chamaeleon* (Blázquez et al., *op. cit.*).

The next day, we recorded egg and nest dimensions. The entrance burrow measured 175 mm in length and the exit angle was acute, resulting in the exit burrow being only about 150 mm. Nest depth, measured from the substrate to the top of the egg mass, was 138 mm. On 30 January 2004, the female weighed 12 g, but only 6.4 g after egg deposition on 04 February. The 11-egg clutch had a total mass of 4.4 g. Egg length averaged 11.7 ± 0.37 mm SD (N = 11). After data collection, we replaced all eggs to their original orientation and re-covered the nest. We recorded nest temperature at the same level as egg depth over the next several days between 0800–2200 h. Mean nest temperature was 27.2 ± 0.92°C (N = 9) during this early period of incubation. We were unable to record nest temperatures beyond 11 February. Hatching occurs in early November in this species (KBK, unpubl. data).

HELODERMA SUSPECTUM (Gila Monster). **PREY**. Gila Monsters are specialized nest predators; their diet includes eggs of ground-nesting birds and reptiles, and juvenile mammals (e.g., *Ammospermophilus leucurus*, *Neotoma albigula*, and *Sylvilagus audubonii*; Beck 2005. Biology of Gila Monsters and Beaded Lizards. University of California Press, Berkeley. 247 pp.). Here, we report prey not previously known for *H. suspectum*, Desert Kangaroo Rats (*Dipodomys deserti*). We describe predation episodes on juvenile kangaroo rats in the field, and we document adult kangaroo rat rescue of nestlings from *H. suspectum* predation.

We radio-tracked *H. suspectum* from March 2000 to August 2004 at a Mojave Desert site near Lake Mead, Nevada (36.5°N, 114.5°W; elev. 600 m; Gienger 2003. Natural History of the Gila Monster in Nevada. Unpubl. MSc Thesis. Univ. of Nevada, Reno. 55 pp.). We located each lizard 2–4 times per day during the active season (March–October). When we found *H. suspectum* surface active, we followed each lizard from a distance of 5–10 m to record successful foraging bouts and specific prey.

At 0710 h on 30 May 2003, we observed an adult female *H. suspectum* excavating an entrance to a rodent burrow complex at the base of a sandy mound (Fig. 1a). After 2 min of excavation, the *H. suspectum* disappeared into the burrow and an adult kangaroo rat ran out of a hole on the other side of the sand mound. Immediately, two altricial (eyes still closed) kangaroo rat pups were observed trying to crawl out of the burrow. The *H. suspectum* then emerged from the burrow behind the pups (Fig. 1b) and seized one pup by the mid-body. After consuming the first pup, along with considerable sand, the Gila Monster then exited the burrow, seized the second pup by the head (Fig. 1c), and consumed it as well.

At 0758 h on 19 June 2003, we observed the same female *H. suspectum* excavating a rodent burrow. After digging for ca. 1 min, the burrow collapsed on itself and the lizard disappeared inside. An adult Desert Kangaroo Rat then sprinted out of a second burrow entrance 70 cm from the collapsed entrance. Three juvenile Desert Kangaroo Rats (pre-weening age; eyes still closed) became visible at the second entrance of the collapsed burrow, with one pup attempting to crawl out of the burrow. The adult Desert Kangaroo Rat (presumably the mother) returned to the opening of the second burrow (Fig. 2a), grabbed the pup that was outside of the burrow (Fig. 2b) and carried it to a third burrow opening located 3.5 m away from the second (Fig. 2c). The mother then stood out-

FIG. 1. Excavation and consumption of a nest of kangaroo rats (*Dipodomys* sp.) by a foraging Gila Monster.

FIG. 2 (opposite). Sequence showing adult female Desert Kangaroo Rat (*Dipodomys deserti*) attempting to rescue her pups from predation by a Gila Monster. The Gila Monster is inside the burrow and the mother removes one of the pups before it can be eaten.

side the third burrow and began a foot-drumming display (Kenagy 1976. J. Mammal. 57:781–785; Randall and Matocq 1997. Behav. Ecol. 8:404–413.) in which she rapidly and repeatedly beat her feet against the sand.

The remaining pups inside the second burrow were squeaking, and the mother returned and moved quickly into the burrow with both the remaining two visible pups and the *H. suspectum*. At 0807 h, the mother emerged from the second burrow (without any pups) and moved over to the third burrow where she had left the rescued pup. At 0820 h, the mother left the third burrow without her pup and moved out of sight. For 20 min, the *H. suspectum* remained inside the second burrow. At 0840 h, squeaking noises emanated from the third burrow where the Desert Kangaroo Rat mother had placed the rescued pup. The Gila Monster remained underground in the second burrow until 0923 h, and then emerged from the burrow (Fig. 2d) and walked to, and into, the third burrow, where it presumably consumed the rescued pup. The *H. suspectum* remained inside the third burrow for ca. 30 min and then emerged above ground. After walking a few steps, the *H. suspectum* licked its face and arched its back with snout pointed upward, a posture Gila Monsters often assume after eating large meals (pers. obs.; Beck 2005, *op. cit.*). This arching posture may help force food items down into the stomach, especially when the stomach is already full.

We were also able to verify nest predation by three other Gila Monsters on kangaroo rats at this Nevada site on four additional occasions. Each time, we were able to verify the genus of the prey (*Dipodomys*) by observing adults leaving the nest or pups attempting to crawl out of the burrow. Most of the time we were not able to identify *Dipodomys* to species, as the adults fled the nest once it was discovered, and Gila Monsters immediately consumed the pups. The possible kangaroo rat species in this area include *D. deserti and D. merriami* (Hall 1946. Mammals of Nevada. University of California Press, Berkeley. 710 pp.), but because these observations were made as part of a larger natural history study of Nevada *H. suspectum*, we did not interfere with lizard foraging activities to determine which of the two *Dipodomys* species were involved. However, the observation of 19 June 2003 is undoubtedly a nest of *D. deserti*, as the kangaroo rat we observed was large and had white hairs on the terminal end of its tail (*D. merriami* are smaller and have black terminal tail hairs).

These six observations suggest that kangaroo rats can constitute an important part of the diet for certain populations of Gila Monsters. Our study site had a considerable amount of sand dunes and Creosote Bush (*Larrea tridentata*), both of which are appropriate habitat elements for *Dipodomys* (Longland and Price 1991. Ecology 72:2261–2273; Schroder 1987. Ecology 68:1071–1083). Most previous ecological studies of Gila Monsters have been conducted at sites lacking sand dunes (Beck 2005, *op. cit.*), hence *Dipodomys* might not be available prey to those populations. Additionally, our Nevada study site lacks conspicuous populations of Desert Cottontail Rabbits (*S. audubonii)*, which constitute the most common food item at other study populations of Gila Monsters (populations in Arizona and Utah; Beck 2005, *op. cit.*).

We thank Ned Dochtermann and Kellie Kuhn for reading early drafts of the manuscript. The Clark County (Nevada) Multi-species Habitat Conservation Program and the Biological Resources Research Center at UNR provided funding.

HEMIDACTYLUS MABOUIA (Tropical House Gecko). **HUMAN-INDUCED INTRODUCTION.** *Hemidactylus mabouia* occurs in urban and other anthropogenic environments as well as varied less disturbed habitats such as tropical rainforest, sand dunes and rock outcrops (Teixeira 2001. Atlântica 23:77–84). A small lizard native to sub-Saharan Africa, it was accidentally introduced to and has colonized most of the South and Central America and Florida (Butterfield et al. 1993. Herpetol. Rev. 24:111–112), Caribbean islands (Townsend and Krysko 2003. Florida Scient. 66:204–208), and Atlantic islands such as Cape Verde (Jesus et al. 2001. J. Herpetol. 35:672–675), Madeira (Jesus et al. 2002. Herpetozoa 15:179–180), São Thomé and Príncipe (Jesus et al. 2005. Mol. Phylogenet. Evol. 34:480–485), and the Abrolhos Archipelago, 70 km off the Brazilian coast (Rocha et al. 2002. Braz. J. Biol. 62:285–291). Populations in the Gulf of Guinea and Macronesian islands are genetically homogenous likely as a result of recent introductions (Jesus et al. 2005, *op. cit.*). Introduction to the Brazilian mainland likely occurred through slave ships from Africa (Vanzolini 1968. Arq. Zool. São Paulo 17:1–84). Here, we describe the recent colonization of the oceanic Trindade Island in the mid-Atlantic Ocean and discuss the likely introduction event. Trindade Island, located 1140 km off the Brazilian coast, is a small volcanic island (5 km × 2.5 km) with an area of 13.5 km^2 and elevations over 600 m (Almeida et al. 2001. *In* Schobbenhaus et al. [eds.], Sítios Geológicos e Paleontológicos do Brasil, pp. 369–377. DNPM, Brasília, Brazil). Originally covered by forests of *Colubrina glandulosa*, fire and domestic grazing (sheep and goats) drove this tree to extinction (Alves 1998. Ilha da Trindade & Arquipélago de Martin Vaz, um Ensaio Geobotânico. Serviço de Documentação da Marinha, Rio de Janeiro, Brazil). Reforestation was begun in 1994, and eradication of goats occurred over the interval 1999–2005 (Alves 2006. *In* Alves and Castro [eds.], Ilhas Oceânicas Brasileiras, da Pesquisa ao Manejo, pp. 83–104. MMA, Brasília, Brazil). Both these domestic grazers are now eradicated, but despite its success, reforestation has ceased. Apart from humans, the only terrestrial vertebrate on Trindade Island is the exotic House Mouse, *Mus musculus*, which is now abundant throughout the island. Since 1957, a small number of Navy personnel (currently ~25 people) who maintain a weather station live on Trindade Island. A boat transports food, equipment, and personnel to the island every two months.

We first observed *H. mabouia* at dusk on 31 December 2006 on a plateau above Príncipe Beach (20.5165°S, 29.3096°W; datum: Córrego Alegre; elev. 140 m) in rock outcrops bordered by the dense, tall (ca. 50 cm high) sedge, *Cyperus atlanticus*. The next day, we captured one *H. mabouia* and found one semi-buried clutch of two eggs and a second clutch of three eggs, both under rocks. Because this species typically deposits two eggs, this may have been a communal nest (Rocha et al., *op. cit.*). After this initial discovery, we made several subsequent observations of adults and juveniles. From January to April 2007, we found up to 10 individuals during search sessions lasting about 1 h, with higher num-

bers recorded near the reforestation area where we first recorded the species.

H. mabouia or their eggs were probably introduced with saplings during the reforestation interval in the late 1990s or early 2000s (Alves 2006, *op. cit.*). As no harbor exists on Trindade and because of its steep topography, saplings were usually transported from boats to the drop areas by helicopters, which would explain the absence of *H. mabouia* near human settlement. Despite the abundance of the terrestrial crab, *Gecarcinus lagostoma,* on the island that could prey on this lizard, a well-established population now exists that is apparently spreading to other areas. We also found 3 *H. mabouia* at sea level on Andradas Beach on different occasions at dusk and at night, roughly 400 m SE from the place where it was presumably first introduced. The nocturnal and crepuscular habit of *H. mabouia* is well known (Rocha et al. 2002, *op. cit.*).

Four specimens were collected and deposited in Setor de Herpetologia, Museu Nacional do Rio de Janeiro (MNRJ 17117, one juvenile collected 1 January 2007; MNRJ 17118 one adult collected 28 February 2007), and in the Museu de Biologia Prof. Mello Leitão, Santa Teresa, Espírito Santo (MBML 2107 and 2108, one juvenile recently hatched and one adult, both collected 19 January 2007). We also found exoskeleton fragments of insects and spiders underneath rocks inhabited by *H. mabouia*. Arthropods are the main prey of *H. mabouia* in Brazil in both urban (Bonfiglio et al. 2006. Biociências, Porto Alegre 14:107–111) and less disturbed coastal environment (Teixeira 2001, *op. cit.*). To our knowledge, no detailed study of the arthropods on Trindade has been undertaken, but the island is home to varied arthropod species including dragonflies, beetles, spiders, flies, moths, grasshoppers, and exotic cockroaches, and may include several introduced species as on Gough Island in the South Atlantic (Jones et al. 2003. Biol. Cons. 113:75–87). *H. mabouia* is expected to expand its distribution throughout the island and arrive at the human settlement soon. As it is the only terrestrial reptile on the island, no conservation concern for related species as a function of *H. mabouia* presence currently exists, as has occurred on other islands (Arnold 2000. Bonn. Zool. Monogr. 46:309–323), but it may represent a threat to endemic invertebrates.

We thank P. Passos (MNRJ) and J. E. Simon (MBML) who assisted us with the identification on *H. mabouia*, and E. G. Hancock and M. P. Hayes for editorial suggestions.

IGUANA DELICATISSIMA (Lesser Antillean Iguana). **MORTALITY.** Major natural disturbances such as hurricanes have been reported responsible for the extirpation of island biotas (Schoener et al. 2004. Proc. Natl. Acad. Sci. USA 101:177–181) and as a mechanism for overwater dispersal (Censky et al. 1998. Nature 395:556). Indeed, these catastrophic disturbances can have profound effects on insular ecosystems and influence current biogeographical patterns (Spiller et al. 1998. Science 281:695–697). Though extirpations and population reductions have been inferred to be caused by catastrophic hurricanes, to our knowledge, direct evidence of hurricane-induced mortality on larger squamates is lacking. Here, we report direct evidence of mortality on *Iguana delicatissima* caused by Hurricane Dean. The eye of Hurricane Dean passed south of Dominica between St. Lucia and Martinique during the morning of 17 August 2007. Hurricane Dean was a Category 2 storm with sustained winds of ca. 160 kph.

On 17 August 2007, hours after Hurricane Dean struck the Commonwealth of Dominica, SV was inspecting damage along the main western coastal road east of Layou Village. Approximately 100 m N of the Layou Quarry is a 10-m wide ravine (15.3989°N, 61.4236°W, datum: WGS84; elev. 20 m), which runs down the slope of the western coastal ridge to the main coastal road. The ravine is typically dry but a 1-m diameter culvert under the road accommodates runoff. On this day, the culvert was blocked with debris, causing runoff to overflow the main coastal road as it made its way toward the sea. Rapidly moving water, ca. 35 cm deep, was choked with debris including branches, leaves, and stones. Within this debris-choked flow, SV observed the head of an adult iguana (ca. 28 cm SVL) on the surface of the road being battered by the onrushing water. The force of the water appeared to have wedged the iguana between rocks. As the iguana lacked signs of rigor mortis or decomposition, we presumed it had recently died. However, whether the iguana was dead prior to becoming wedged in the rocks or it drowned as a result of being trapped in the rushing water was unclear.

On 19 August 2007, CRK was inspecting hurricane damage on a communal iguana nesting area (ca. 72 m^2) located on the coastal slope between the main western coastal road and Batali Beach (15.4497°N, 61.4478°W; elev. 16 m). The storm caused the upper portion of the ridge to fail, resulting in a landslide of large boulders (up to 2 m long; 1 m high) and trees. The heavy rains also caused severe erosional rutting up to 1.5 m deep. Twenty-five torn and crushed iguana eggs with near-term neonates were counted scattered about the lower and middle portions of the slope. One dead hatchling iguana was discovered partially unearthed while trapped in a 2-cm wide collapsed exit burrow located toward the lower portion of the slope. A group of dead hatchlings was found 5 m above the first hatchling. Three iguanas in the group were visible, protruding partially from the surface of the slope while 14 others were entombed just under the surface. All hatchlings were facing the same outward direction and appeared to be in the process of exiting the same ca. 10 cm wide collapsed tunnel of compressed soil. Three hatchlings had crushed skulls. These animals are presumed to have died in their exit burrow as a result of the landslide.

Hurricane season in the Caribbean is typically from 1 June to 30 November, which encompasses the incubation and emergent period for *I. delicatissima* hatchlings, and therefore can impact not only existing iguana populations but also the annual recruitment of hatchlings into these populations. In fact, hurricanes have been implicated in population declines of *I. delicatissima* on the Petite Terre Islands in the French West Indies (Lorvelec et al. 2004. Rev. Ecol. Terre Vie 59:331–344). By reporting mortality in multiple life stages (egg, hatchling, adult), our observations provide evidence for the ecological mechanisms of such population declines caused by catastrophic disturbance.

We thank Arlington James and the staff at the Division of Forestry, Wildlife, and Parks for their support and permission to conduct this study. Glenn Gerber provided valuable comments on the original draft of this note. This observation was made while conducting *I. delicatissima* research on Dominica funded through the center for Conservation and Research for Endangered Species (CRES) at the Zoological Society of San Diego.

LEIOCEPHALUS CARINATUS (Northern Curly-tail Lizard). **SAP FEEDING**. Despite their widespread distribution and locally high densities throughout the Caribbean, the natural history of lizards in the genus *Leiocephalus* is relatively poorly known. The few studies of *Leiocephalus* diet suggest that these lizards are omnivorous, eating vegetation, insects, and vertebrates, including lizards (Fong G. and Del Castillo 2002. Herpetol. Rev. 33:205–206; Jenssen et al. 1989. Anim. Behav. 38:1054–1061; Micco et al. 1997. Herpetol. Nat. Hist. 5:147–156; Schoener et al. 1982. Oecologia 53:160–169; Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville. 720 pp.). They can also be scavengers (Iverson and Smith 2006. Herpetol. Rev. 37:345–346). Here, we describe a previously unreported potential food source for *Leiocephalus carinatus*.

On 25 June 2007, we observed an adult *L. carinatus* (sex unknown) feeding on the sap of a Bay Cedar (*Suriana maritima*) on Alligator Cay, Exumas, Bahamas (24.3931°N, 76.6428°W, datum: WGS84; elev. 2 m; see Knapp 2001. J. Herpetol. 35:239–248 for description of the island). The sap originated from a crack in a branch of the Bay Cedar. The lizard was observed to lick the surface of the Bay Cedar branch repeatedly at the location of sap "bubbles," which disappeared when the lizard licked them, suggesting that the tongue was used to consume the sap, rather than being used in exploratory tongue-flicking behaviors (digital video available from authors). To date, sap feeding has been documented in only one other lizard, the gecko *Gehyra australis* (Letnic and Madden 1997. West. Austr. Nat. 21:207–208; see review by Cooper and Vitt 2002. J. Zool. 257:487–517). Combined with the previous observations on the diets of *Leiocephalus*, our results suggest that these lizards are more broadly omnivorous than previously recognized.

PLESTIODON REYNOLDSI (Florida Sand Skink). **ALBINISM**. *Plestiodon reynoldsi*, a federally threatened species, is restricted to upland scrub and sandhill habitats in central Florida (McCoy et al. 1999. Conserv. Biol. 13:190–194). On 1 September 2007, we collected an albino juvenile (30.5 mm SVL, 27.0 mm tail; 0.18 g) in an Inopina Oak (*Quercus inopina*) scrubby flatwood at Archbold Biological Station, Lake Placid, Highlands Co., Florida, USA (27.1346°N, 81.3597°W, datum: WGS84; elev. 40 m). This individual was recaptured at the same location on 16 and 19 September 2007. Albinism has never before been reported in *P. reynoldsi*. The background color was pink with a paler dorsal area and little contrast between dorsal and either the lateral or ventral coloration (Fig. 1). Juveniles are typically gray-brown with a distinctly dark brown lateral band from the snout to the tip of the tail on each side of the body. The heart, major circulatory system vessels, and parts of the digestive system were visible through its ventral side. Non-albino juveniles have a pattern of small, dark brown spots on a gray-brown light background on top of the head, whereas this albinistic juvenile had but one slightly darker spot on one of the parietal scales against a pale pink bakground. The irises of the albino juvenile were red (black in typical juveniles). We deposited digital color images of the specimen in the Calphotos database (http://calphotos.berkeley.edu/).

SCELOPORUS POINSETTII (Crevice Spiny Lizard)**. DIET.** Lizards of the genus *Sceloporus* are mainly insectivorous (e.g., Ballinger 1978. Southwest. Nat. 23:641–649; Goldberg and Bursey 1990. J. Herpetol. 24:446–448; Pough 1973. Ecology 54:837–844), with notable herbivorous exceptions (*Sceloporus torquatus torquatus;* Búrquez et al. 1986. J. Herpetol. 20:262–264; *S. poinsettii*; Ballinger et al. 1977. Amer. Midl. Nat. 97:482–484). Ballinger et al. (*op. cit.*) described a shift in diet preference from insects to plants during ontogeny in *S. poinsettii*. We examined the diets of 21 *S. poinsettii* from northwestern Mexico, including 11 juveniles (44–93 mm SVL), 5 young adults (83–93 mm SVL), and 5 older adults (93–100.2 mm SVL), allowing examination of any potential ontogenetic dietary shift. As part of a taxonomic and

distributional survey of the Chihuahuan Desert and surrounding areas (Lemos-Espinal et al. 2004. Introducción a los Anfibios y Reptiles del Estado de Chihuahua. UNAM/CONABIO, Ciudad de México. 128 pp.), specimens were captured in spring and summer 2001 and 2002 from various localities in northwestern Chihuahua, México. We removed their stomachs by dissection for dietary analysis. SVL, head-length (HL), and head-width (HW) were measured with digital calipers to the nearest 0.1 mm. We identified prey items to the lowest possible taxonomic category, usually order. We measured prey length and width with digital calipers to the nearest 0.1 mm and calculated prey volumes using the formula for a prolate spheroid (Vitt et al. 2005. Herpetol. Monogr. 19:137–152).

The *S. poinsettii* that we examined consumed nearly 100% insect material, with ants being most important numerically (156) and beetles being the most important volumetrically (37.83%) (see Table 1). We found no significant relationships among SVL, HL, or HW; and prey length, width, or volume (all $P > 0.30$).

Our findings are contrary to those of Ballinger (*op. cit.*) and Ballinger et al. (*op. cit.*) who report ontological diet shifts from insects to plants. Our samples showed no such shift. Thus, ontogenetic dietary shifts in *S. poinsettii* seem to vary among populations.

LEMOS–ESPINAL**, Laboratorio de Ecología, Tecnología y Prototipos, Facultad de Estudios Superiores Iztacala, UNAM, Apartado Postal 314, Avenida de Los Barrios No. 1, Los Reyes Iztacala, Tlalnepantla, Estado de México, 54090 México (e-mail: lemos@servidor.unam.mx).

TRACHYDOSAURUS RUGOSUS ASPER (Shingle Back, Boggi, or Pine-cone Lizard) **PREDATION**. *Trachydosaurus rugosus*, including four subspecies, is a lizard widespread across much of the southern half of continental Australia and selected western offshore islands (Shea 1992. Unpubl. Ph.D. thesis, University of Sydney; Shea 2000. *In* Hauschild et al. [eds.], Blauzungenskinke. Beitrage zu *Tiliqua* und *Cyclodomorphus*, pp. 108–112. Natur und Tier Verlag, Munster), but few records of its predators exist. This note documents an observation of predation on *T. r. asper* by Wedge-tailed Eagles, *Aquila audax*.

At ~0900 h on 8 December 2007, MD observed 3 *A. audax* ca. 40 km N of Conargo, New South Wales, on Conargo-Carrathool Road ca. 400 m S of its intersection with Steam Plains Road (35.0708°S, 145.3779°E, datum: WGS84; elev. 110 m). Two were sitting on a stock watering-trough drinking, and the third was circling in the air ~100 m distant from the other two. The latter was observed to swoop to the ground, where it stood erect with its head above the grass; when approached by the observer to within 25 m, it flew into the air ~4 m above the ground with an adult *T. r. asper* (ca. 25 cm SVL) in its talons, and briefly hovered for 2–3 seconds until the observer veered off. The *A. audax* then settled back on the ground, where it was joined by one of the other two eagles; both then commenced feeding on the lizard. Habitat was very open *Acacia pendula* woodland with sparse graminoid herbaceous layer; air temperature was ~22°C, with no cloud cover and no wind. *A. audax* is a well-known scavenger of road-kills and farm animal mortalities, and as a predator of small wallabies and introduced rabbits, however predation on reptiles is somewhat unusual. Interestingly, an *A. audax* was observed to seize a live adult Eastern Brown Snake, *Pseudonaja textilis*, in March 2007, ca. 16 km S of Riverina Highway on Aratula Road (Katrina Molesworth, pers. comm.), which is ca. 50 km SW of the above locality. There has been an extended drought in the region over the previous four years, which might partly explain the willingness of *A. audax* to take reptilian prey in this region, as rabbits and road-kills are currently few.

We thank M. Hayes for editorial suggestions.

TROPIDURUS OREADICUS (Neotropical Ground Lizard). **DIET**. *Tropidurus oreadicus* occurs in savanna-like habitats. In Belém, it is usually seen on the trunks of isolated trees, and in some places, on walls and fences; in Amazonia, the species is also frequently terrestrial (Ávila-Pires 1995. Lizards of Brazilian Amazonian [Reptilia:Squamata]. Zool. Verhandelinger 299:1–706). Food consists of diverse insect arthropods, but can sometimes include centipedes, millipedes, and plant matter (Ávila-Pires, *op. cit.*). However, arthropod prey are typically not identified to species. Here I describe an observation of an adult *T. oreadicus* preying on an adult centipede, *Scolopendra viridicornis*.

At 1120 h on 13 July 2006, I found an adult male *T. oreadicus* (ca. 110 mm SVL) running in the leaf litter with an adult (ca. 85

mm) *S. viridicornis* in its mouth in a urban park of Museu Paraense Emílio Goledi (MPEG) (1.4523°S, 48.4762°W, datum: WGS84, elev. 25 m), where the trees are closely spaced but significant open areas still exist. The *T. oreadicus* exhibited some difficulty ingesting the centipede because its caudal appendices and the last two pair of legs were protruding from the lizard's mouth for 9 min before the lizard was able to completely swallow it.

My observation reveals that medium-sized (> 90 mm) centipedes can be vulnerable to medium-sized lizards, like *Tropidurus* species. In 71 *T. oreadicus* stomachs, centipedes were present in six (Ávila-Pires, *op. cit.*). Scolopendromorph centipedes can deliver a painful bite that has potential medical implications for humans and have been reported to sometimes prey upon small lizards (Lewis 1981. The Biology of Centipedes. Cambridge University Press, Cambridge, United Kingdom. 476 pp.), so they may present some risk that is in part related to size. *Scolopendra viridicornis* is a common large or medium-sized species in Brazil that can also be found in Guyana, Venezuela, Bolivia, Paraguay, and Argentina (Adis 2002. *In* Adis [org.], Amazonian Arachnida and Myriapoda—Identification Keys to All Classes, Orders, Families, Some Genera, and Lists of Known Terrestrial Species. Pensoft Publishers, Sofia, Bulgaria. 590 pp.).

Submitted by **FERNANDO DA SILVA CARVALHO-FILHO,** Departamento de Biologia, Universidade Federal do Pará, Rua Augusto Corrêa, 01, CEP 66040-170, Guamá, Belém-PA, Brazil; e-mail: fernanbio@yahoo.com.br.

TROPIDURUS OREADICUS (Neotropical Ground Lizard). ***CNEMIDOPHORUS LEMNISCATUS*** (Rainbow Whiptail). **PREDATION.** *Tropidurus oreadicus* and *Cnemidophorus lemniscatus* are common lizards in open and sunny areas in eastern Amazonia (Ávila-Pires 1995. Lizards of Brazilian Amazonian (Reptilia: Squamata). Zool. Verhandelinger 299:1–706). Hawks of the genera *Leucopternis* and *Gampsonyx* and the Common Egret, *Egretta alba*, are documented avian predators of *C. lemniscatus* (Hoogmoed 1973. Biogeographica 4:1–419; Ávila-Pires, *op. cit.*), but few avian predators of *T. oreadicus* have been reported (Ávila-Pires, *op. cit.*). Here, I describe an observation of Guira Cuckoo (*Guira guira*) predation on *T. oreadicus* and *C. lemniscatus* from northern Brazil.

At 1520 h on May 2006, a clear sunny day, I observed a flock of 11 adult *G. guira* foraging on mowed grass on the campus of Universidade Federal do Pará, Belém, Pará State, Brazil (1.47°S, 48.45°E). During my observation, I noted a disturbance in bird group as one member of flock arose with a dead juvenile of *T. oreadicus* (ca. 5 cm SVL) in its bill. The *G. guira* began to run to avoid another member of its flock that tried to steal the lizard. When the *G. guira* with the lizard had distanced itself from its congener, it swallowed the lizard by head first. The entire predation episode took 9 min.

Forty minutes later, I noted another *G. guira* with a *C. lemniscatus* (ca. 10 cm SVL) in its beak. The lizard, held sideways by its neck, was entirely limp (including tail and limbs) and seemed dead. The lizard remained limp during the entire 2 min observation period, after which the *G. guira* flew out of view with its prey to a nearby tree, because three members of its flock simultaneously tried to steal the lizard.

Our observations suggest that *G. guira* may be important lizard predators in open habitats. The Guira Cuckoo, one of the best-known abundant birds in eastern Brazil, is common in parks, cities, pastures, and plantations, but is absent from most of Amazonia because it avoids continuous forests; it is also frequent in grasslands along the Amazonian estuary (Sigrist 2006. Aves do Brasil, uma Visão Artística. Brazil, São Paulo. 672 pp.). This bird is an active forager, preying on insects and small vertebrates such as frogs, mice, and small birds (Martins and Donatelli 2001. Ararajuba 9:89–94; Sigrist 2006, *op. cit.*), but few records exist of its preying on lizards.

Submitted by **FERNANDO DA SILVA CARVALHO-FILHO,** Departamento de Biologia, Universidade Federal do Pará, Rua Augusto Corrêa, 01, CEP 66040-170, Guamá, Belém-PA, Brazil; e–mail: fernanbio@yahoo.com.br.

SQUAMATA — SNAKES

BOTHROPS ASPER (Terciopelo). **PREDATION.** Few predators of neotropical lanceheaded pitvipers (*Bothrops*) have been identified (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York. xviii+870+[28] pp.). I herein report predation on *B. asper* by a land crab (*Gecarcinus quadratus*, Gecarcinidae). On 26 August 2003 at 2000 h I found a juvenile *B. asper* (SVL ca. 60 cm) coiled up next to a trail in the coastal rain forest near La Leona station, Corcovado National Park, Peninsular de Osa, Costa Rica. When I passed the spot again at 2230 h, the snake was dead, with the anterior half of its body laying inside a hole in the ground. The hole turned out to be the burrow of a large land crab, which was found at the end of the burrow. It had already eaten the snake's head and anterior parts of the body. The short period between the two observations makes it unlikely that the snake was killed otherwise and only subsequently eaten by the crab. *Gecarcinus quadratus*, which is considered a seed and seedling predator, is abundant in the coastal forest of the Corcovado National Park, with up to six crabs / m^2 (Sherman 2002. J. Trop. Ecol. 18:67–89), and can be found several hundred meters from the coast inside the forest (pers. obs.). It is therefore possible that this crab is a regular, though opportunistic, predator of *B. asper* and other snakes in this area.

NECTURUS MACULOSUS (Common Mudpuppy). USA: NORTH CAROLINA: ALLEGHANY CO.: Adult caught in minnow trap in New River at New River State Park, 18.8 km airline NW Sparta. 09 March 2007. Lori Williams, Ed Corey, and New River State Park staff, Jeff Matheson, and Paul Bailey. First documented record in the New River for Alleghany County (Williams 2007. NC NHP Special Animal Survey Form). Specimen verified by Jeffrey C. Beane. North Carolina State Museum of Natural Sciences photo voucher (accession number 12194). Closest previous historical record is one occurrence from the New River at New River State Park in Ashe Co., North Carolina, 16 km airline SSW (Williams and Corey. 2007. Herpetol. Rev. 38:472.)

Submitted by **LORI A. WILLIAMS**, North Carolina Wildlife Resources Commission, 177 Mountain Laurel Lane, Fletcher, North Carolina 28732, USA; and **J. EDWARD COREY III**, North Carolina Division of Parks and Recreation, 12700 Bay Leaf Church Road, Raleigh, North Carolina, 27614-9633, USA.

NOTOPHTHALMUS VIRIDESCENS (Red-spotted Newt). CANADA: ONTARIO: Lake of the Woods. Single eft found under barrel when outhouse was renovated 02 September 1991, (49.4352111°N, 94.0198333°W). University of Manitoba, Department of Zoology (MZH27). Verified by K. W. Stewart, University of Manitoba. Collected by W. G. Franzin (Department of Fisheries and Oceans, Winnipeg) along with a *Plethodon cinereus*. This specimen is from the western-most limit of the species' range, with the nearest record in the Ontario Ministry of Natural Resources database at 49.4236111°N, 94.0877778°W (Oldham and Weller 2000. Ontario Herpetofaunal Atlas. Natural Heritage Information Centre, Ontario Ministry of Natural Resources. http://www.mnr.gov.on.ca/MNR/nhic/herps/ohs.html (updated 15-01-2001). http://nhic.mnr.gov.on.ca/herps/salamanders.html http://nhic.mnr.gov.on.ca/herps/Northern_Ont/Salamanders/cene.jpg). See also the generalized range map by MacCulloch (2002. Amphibians and Reptiles of Ontario. Royal Ontario Museum, Toronto, Ontario. 168 pp.).

Submitted by **GAVIN F. HANKE**, Royal British Columbia Museum, 675 Belleville Street, Victoria, British Columbia, V8W 9W2 Canada; e-mail: ghanke@royalbcmuseum.bc.ca.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: ARKANSAS: DALLAS CO.: 5.6 km S Sparkman off St. Hwy 7 at Brushy Creek (Sec. 15, T10S, R17W). 07 May 1986. Henry W. Robison. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30829). New county record filling a distributional gap between Clark and Cleveland counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.), and leaving only Lafayette County without documentation of *N. v. louisianensis* for all of south Arkansas.

Submitted by **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@saumag.edu); and **CHRIS T. MCALLISTER**, Department of Physical and Life Sciences, Chadron State College, Chadron, Nebraska 69337, USA (e-mail: drctmcallister@aol.com).

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: MISSOURI: PERRY CO.: larva found in farm pond near PCR 606, Biehle (37.644444°N, 89.8575°W; WGS84). 02 September 2006. Collected by Richard L. Essner, Jr., Paul E. Brunkow, Roma Patel, Daniel L. Huff, and James H. Robins. Verified by Ralph W. Axtell, Southern Illinois University Edwardsville (SIUE 2949). New county record. This is the first report from Perry County (Daniel and Edmond 2008. Atlas of Missouri Reptiles and Amphibians for 2007).

Submitted by **RICHARD L. ESSNER, JR.** (e-mail: ressner@siue.edu)**, PAUL E. BRUNKOW** (e-mail: pbrunko@siue.edu), **ROMA PATEL, DANIEL L. HUFF,** Department of Biological Sciences, Southern Illinois University Edwardsville, Illinois, 62026, USA; and **JAMES H. ROBINS** Department of Biology, Southeast Missouri State University, Cape Girardeau, Missouri, 63701, USA (e-mail: jhrobins@semo.edu).

PLETHODON GLUTINOSUS (Slimy Salamander). USA: ILLINOIS: HAMILTON CO.: Hamilton County State Fish and Wildlife Area, forested hillside ca. 10 m S of Kiwanis Point Picnic Area (38.060277°N, 88.4°W). 06 Oct 2007. Cy L. Mott. Verified by Ronald A. Brandon. SIUC H-8683. Adult specimen. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.).

Submitted by **CY L. MOTT**, Cooperative Wildlife Research Laboratory, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA; e-mail: cm8755@siu.edu.

PLETHODON MISSISSIPPI (Mississippi Slimy Salamander). USA: TENNESSEE: GIBSON CO.: Bradford (36.03358°N, 88.47916°W; datum WGS 84). 04 February 2008. Joshua M. Hall. Verified by A. Floyd Scott. Austin Peay State University's David H. Snyder Museum of Zoology (APSU 18883 [color photo]). Two adult specimens found underneath damp log in heavily wooded area; one photographed and released. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Austin Peay State Univ. Misc. Publ. 12:1–94; Redmond and Scott 1996. Atlas of Amphibians in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. http//www.apsu.edu/amatlas/).

Submitted by **JOSHUA M. HALL**, 4105 Caldwell Drive, Milan, Tennessee 38358, USA.

ANURA – FROGS

ATELOGNATHUS JEINIMENENSIS. ARGENTINA: SANTA CRUZ: DEPARTAMENTO LAGO BUENOS AIRES: 71 km by road (50 km air line) S of Los Antiguos (46.977444°S, 71.828222°W; datum: WGS84; 1256 m elev.). 23 March 2007. A. Scolaro. Herpetological collection, Museo de La Plata, Buenos Aires (MLP A 4994–4999, three adults and three juveniles, collected at a small stream in the arid Patagonian steppe). Verified by J. D. Williams. The species was only known from the type locality, a small pond in the Reserva Nacional Lago Jeinimeni, southern Chile, 46.8332222°S, 71.99925°W (Meriggio et al. 2004, Bol. Mus. Nac. Hist. Nat. Chile 53:99–123), and is listed as Near Threatened by the IUCN, Conservation International, and NatureServe (2006, Global Amphib-

ian Assessment. <www.globalamphibians.org>). The habitat differs from the type locality in lacking a *Nothofagus pumilio* forest. First country record, extends the known range of the species to the E of the Andes, 20.7 km air line SE from the type locality.

Submitted by **ALEJANDRO SCOLARO, LIZA B. MARTINAZZO,** and **NESTOR G. BASSO,** Centro Nacional Patagónico, Blvd. Brown 2825, 9120 Puerto Madryn, Chubut, Argentina.

BATRACHYLA ANTARTANDICA (Marbled Wood Frog). CHILE: DE LOS RIOS REGION (XIV): Valdivia Province, San Pablo de Tregua Farm (39.6127778°S, 72.0911111°W) 30 km by road from Panguipulli City. 09 December 2007. C. Cuevas and Y. Ugarte. Colección de Anfibios del Instituto de Zoología, Universidad Austral de Chile, Valdivia (IZUA 0001, female). The locality is in Pre-Andean Mountain (692 m elev.) with native forest dominated by *Nothofagus dombeyi*, *Laurelia philippiana*, and *Saxogotea conspicua*.Verified by R. Formas. *Batrachyla antartandica* has a wide distribution along the Andes (54.9333333°S to 40.5833333°S), and Coastal Range (42.6333333°S to 39.3833333°S) (Atalah and Sielfeld 1976. Anales del Instituto de la Patagonia [Chile] 7:169–170; Díaz and Ortiz 2003. Revista Chilena de Historia Natural 76:509–525). Northernmost record for the species along the Andes Range, extends distribution 102 km N from Puyehue (40.7497222°S, 72.2008333°W) the closest record previously known (Formas 1979. *In* W. E. Duellman [ed.], The South American Herpetofauna, pp. 341–379. Monograph 7, Museum of Natural History, University of Kansas).

Submitted by **CÉSAR C. CUEVAS**, Instituto de Zoología, Universidad Austral de Chile, Casilla 567, Valdivia-Chile (e-mail: ccuevas@uach.cl); and **YURI E. UGARTE**, Instituto de Botánica, Universidad Austral de Chile, Casilla 567, Valdivia-Chile (e-mail: yuriugarte@uach.cl).

BUFO OLIVACEOUS (Olivaceous Toad): INDIA: HARYANA: Gurgaon District: Sultanpur Bird Sanctuary (28.6166667°N, 77.0666667°E, 230 m elev.). 16 August 2006. Sukumar Ray and Sukesh Ray. ZSIC A 10667. Verified by Saibal Sengupta and compared with syntypes, ZSIC 3523–3525 from Balochistan, Pakistan. Adult male, SVL 54.6 mm. Found on moist ground, ca. 20 m from wetland. Previously known from Baluchistan Province, Pakistan (Blanford 1874. Ann & Mag. nat. Hist. Ser 414:35). Eastward range extension by ca. 750 km and a new record for India. We are grateful to the Director, ZSI, for support.

Submitted by **SUKUMAR RAY** and **KAUSHIK DEUTI**, Zoological Survey of India, 27 Jawaharlal Nehru Road, Kolkata 700 016, West Bengal, India; e-mail: kaushikdeuti@rediffmail.com.

CACOSTERNUM PLIMPTONI (Plimpton's Dainty Frog). ETHIOPIA: OROMIA REGION: Awash River, 40 km SW of Addis Ababa (08.84635°N, 38.4570333°E), 2048 m elev. 24 July 2006. B. M. Zimkus, R. Kerney, and D. Pawlos. AAU A2008–324–346 (23 specimens). Muti Deyo, 53 km S of Addis Ababa (08.6536333°N, 38.58155°E), 2108 m elev. 24 July 2006. B. M. Zimkus, R. Kerney, and D. Pawlos. AAU A2008-356–360 (5 specimens). Verified by D. C. Blackburn. Originally documented from northern Tanzania and highlands of Kenya (Channing et al. 2005. African J. Herpetol. 54[2]:139–148). New country records for Ethiopia, substantially extending range ca. 1300 km NNE from type locality at Musabi Plain in Serengeti National Park, Tanzania. Original species description postulated that populations isolated in Ethiopia as *C. boettgeri*, were in fact, *C. plimptoni*; additional study required to confirm this.

Submitted by **BREDA M. ZIMKUS,** Department of Organismic and Evolutionary Biology, Harvard University, 26 Oxford Street, Museum of Comparative Zoology, Cambridge, Massachusetts 02138, USA; e-mail: bzimkus@oeb.harvard.edu.

HEMIPHRACTUS SCUTATUS (Spix's Horned Treefrog). BOLIVIA: PANDO: Nueva Esperanza, Province Federico Román (10.0635278°S, 65.4026111°W; 114 m elev.). 02 November 2006. A. Muñoz. Museo de Historia Natural Alcide d'Orbigny Cochabamba, Bolivia (MHNC AF 1227, Digital photo, an adult specimen found dead in forest litter). Verified by I. De la Riva. Previously known from Brazil (Porto Walter and Juruá); Colombia; Ecuador (Parque Nacional Yasuní), and Perú, (Ucayali, Iquitos and Ampiyacu), (Lehr 2001. Herpetol. Rev. 32:130–132; InfoNatura: Birds, mammals, and amphibians of Latin America. 2004: NatureServe. Available: http://www.natureserve.org/infonatura; Vitt and Caldwell 1996. Inventário e Ecologia da Herpetofauna da Amazônia: Rio Juruá, Porto Walter, Acre, Brazil. Report Proj. NSF Project DEB-9505518, unpublished report). First country record extends known distribution 164 km E from range cited by Coloma et al. 2004. (IUCN Red List of Threatened Species. <www.iucnredlist.org>).

Submited by **ARTURO MUÑOZ-SARAVIA**, Museo de Historia Natural Alcide d'Orbigny, Casilla Postal 843, Cochabamba, Bolivia; e-mail: hyla_art@yahoo.com.

HYLA CINEREA (Green Treefrog). USA: ARKANSAS: Lincoln Co.: 1.6 km S Glendale off St. Hwy 54 at Sanders Creek (Sec. 8, T19S, R8W). 14 June 2003. Henry W. Robison. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30830). New county record filling a distributional gap between Cleveland (Robison and McAllister 2007. Herpetol. Rev. 38:245–246) and Desha counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

McALLISTER**, Department of Physical and Life Sciences, Chadron State College, Chadron, Nebraska 69337, USA (e-mail: drctmcallister@aol.com).

HYLA VERSICOLOR (Gray Treefrog). USA: ARKANSAS: Searcy Co.: Off AR 14, ca. 2 km down Ramblewood Trail by private residence. 12 June 2007. J. S. Hicks, M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 30743). First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univeristy of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MATTHEW B. CONNIOR** and **IDUN GUENTHER**, Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467, USA; e-mail: matthew.connior@smail.astate.edu.

LITHOBATES CATESBEIANUS (American Bullfrog). USA: ARKANSAS: SEARCY CO.: Off AR 14, ca. 2.2 km down Ramblewood Trail in small drainage creek (36.0566°N, 92.6002°W; NAD 83). 07 October 2007. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 30805). First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MATTHEW B. CONNIOR,** Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467, USA; e-mail: matthew.connior@smail.astate.edu.

LITHOBATES CLAMITANS (Green Frog). USA: ARKANSAS: SEARCY CO.: Off AR 14, ca. 2.2 km down Ramblewood Trail in small drainage creek (36.0566°N, 92.6002°W; NAD 83). 06 October 2007. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 30806). First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univeristy of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MATTHEW B. CONNIOR,** Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467, USA; e-mail: matthew.connior@smail.astate.edu.

LITHOBATES CLAMITANS (Green Frog). USA: TENNESSEE: GIBSON CO.: Bradford (36.03175°N, 88.47956°W: datum WGS 84). 08 February 2008. Joshua M. Hall. Verified by A. Floyd Scott. Austin Peay State University's David H. Snyder Museum of Zoology (APSU 18882 [color photo]). One adult specimen found underneath damp log in drainage ditch. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Austin Peay State Univ. Misc. Publ. 12:1–94; Redmond and Scott 1996. Atlas of Amphibians in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. http://www.apsu.edu/amatlas/).

Submitted by **JOSHUA M. HALL**, 4105 Caldwell Drive, Milan, Tennessee 38358, USA.

LITHOBATES PALUSTRIS (Pickerel Frog). USA: ARKANSAS: VAN BUREN CO.: Choctaw at Choctaw Creek off St. Hwy 65 (Sec. 12, T10N, R14W). 10 July 1990. M. Evans. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30828). New county record partially filling a distributional hiatus in north-central Arkansas among Cleburne and Pope counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

Submitted by **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@saumag.edu); and **CHRIS T. MCALLISTER**, Department of Physical and Life Sciences, Chadron State College, Chadron, Nebraska 69337, USA (e-mail: drctmcallister@aol.com).

LITHOBATES SYLVATICUS (Wood Frog). USA: ILLINOIS: GALLATIN CO.: Shawnee National Forest, vernal pond ca. 1 km from Pounds Hollow Rd. on York Lane Rd. (37.6038889°N, 88.2627778°W). 26 March 2007. Cy L. Mott. Verified by Ronald A. Brandon. SIUC H-8685. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.).

Submitted by **CY L. MOTT**, Cooperative Wildlife Research Laboratory, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA; e-mail: cm8755@siu.edu.

LITHOBATES SYLVATICUS (Wood Frog). USA: OHIO: GREENE CO.: Spring Valley Township: Caesar Creek Wildlife Area. 3.5 km SE of Roxanna from floodplain of Caesar Creek. (39.57876°N, 83.93340°W). 03 June 2007. Jeffrey G. Davis. Verified by John W. Ferner. Cincinnati Museum Center, Frederick and Amye Geier Research and Collections Center (CMC 10799). New county record (Davis and Menze 2000. Ohio Frog and Toad Atlas. Ohio Biol. Surv. Misc. Contr. No. 6).

Submitted by **JEFFREY G. DAVIS**, Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA; e-mail: anura@fuse.net.

NANORANA CHAYUENSIS (Chayun Bull Frog). INDIA: WEST BENGAL: DARJEELING DISTRICT: Neora Valley National Park: hill stream, 3 km from Kolakham village (27.1138889°N, 88.8905556°E, 1860 m elev.). 07 August 2007. A. K. Ayyaswamy and K. Deuti. ZSIC A10683. Verified by A. Ohler. Adult female (SVL 76.12 mm) on boulders under dense bushes, ca. 2 m from hill stream. Previously known from holotype (CIB 7319524), collected from Chayu (28°25'N, 97°06'E, 1540 m elev.), Xizang Zizhiqu Dixing, China (Ye 1977. Acta Zool. Sinica 23:58, 62). Westward range extension by ca. 920 km (map distance), and new record for India. We thank the Director, Zoological Survey of India, for support, West Bengal Forest Department for permission, and Raj Bose, Help Tourism, for logistic facilities.

Submitted by **KAUSHIK DEUTI** and **ANAND KUMAR AYYASWAMY**, Zoological Survey of India, Nizam Palace Office, 234/4 A. J. C. Bose Road, Kolkata 700 020, India; e-mail: kaushikdeuti@rediffmail.com.

NASIRANA ALTICOLA (Annandale's Frog). BANGLADESH: RANGAMATI DISTRICT: Kaptai National Park (22.5°N, 92.2°E; 201–210 m elev). 13 July 2007. A. H. M. Ali Reza. Wildlife Laboratory, Department of Zoology, Jahangirnagar University, Savar, Dhaka (JU 0082). Photograph deposited at USDZ, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 1.24). Verified by Guin Wogan. First verified locality for Rangamati District. Reported from Dhaka (ca. 200 km NE) with no voucher specimens or photograph (Dutta 1997. Amphibians of India and Sri Lanka. Odyssey Publishing House, Bhubaneswar, India. xiii + 342 + xxii pp.). Mentioned in herpetofaunal list of Bangladesh, without voucher specimens, photographs, or locality information (Khan 2004. Cobra 57:1–31). Fieldwork supported by Cleveland Metroparks Zoo and Rufford Small Grants Foundation and conducted with permission of Bangladesh Forest Department (CCF [Wildlife]/2M–47/2006). I thank Md. Kamal Hossain from JU for assistance in the field.

Submitted by **A. H. M. ALI REZA**, Department of Natural Resources Management, Texas Tech University, Lubbock, Texas

79409, USA, and Department of Zoology, Jahangirnagar University, Dhaka 1342, Bangladesh; e-mail: wild_reza@yahoo.com.

OCCIDOZYGA BOREALIS (Northern Trickle Frog). BANGLADESH: BANDARBAN DISTRICT: Bandarban Hill District (22.1666667°N, 92.2166667°E; 195–210 m elev.). 16 July 2007. A. H. M. Ali Reza. Wildlife Laboratory, Department of Zoology, Jahangirnagar University, Savar, Dhaka (JU 0088). Photograph deposited at USDZ, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 1.23). Verified by Guin Wogan. First country record for species. Nearest population reported from Nameri National Park, Assam, > 500 km N (Pawar and Birand 2001. A Survey of Amphibians, Reptiles, and Birds in Northeast India. CERC Tech. Rep. No. 6, Centre for Ecological Research and Conservation, Mysore, India. 118 pp.). Fieldwork financed by Cleveland Metroparks Zoo and Rufford Small Grants Foundation, and was conducted with permission of Bangladesh Forest Department (CCF [Wildlife]/2M–47/2006). Thanks are due to Md. Kamal Hossain for assistance in the field.

Submitted by **A. H. M. ALI REZA**, Department of Natural Resources Management, Texas Tech University, Lubbock, Texas 79409, USA, and Department of Zoology, Jahangirnagar University, Dhaka 1342, Bangladesh; e-mail: wild_reza@yahoo.com.

PHRYNOBATRACHUS BULLANS (Bubbling Puddle Frog). ETHIOPIA: SOUTHERN NATIONS, NATIONALITIES, AND PEOPLE'S REGION: East shore of Lake Awassa (07.04845°N, 38.4609833°E), 1692 m elev. 25 June 2006. B. M. Zimkus, R. Kerney, and D. Pawlos. AAU A2008–032. KENYA: NYANZA PROVINCE: Homa Bay (0.5166667°N, 34.45°E). 14 May 2003. D. R. Buchholz, T. B. Hayes, A. Espira, K. M. Haston, and M. Kahindi. MVZ 238716. TANZANIA: MWANZA REGION: Lamadi, near Lake Victoria (02.2434167°N, 33.8522167°E), 1145 m elev. 23 May 2000. D. R. Buchholz, T. B. Hayes, A. Vonk, E. Marquez, and A. Espira. MVZ 234151. All specimens verified by D. C. Blackburn. Originally documented from central Tanzania in the Arusha, Tabora, and Singida regions (Crutsinger et al. 2004. Afr. Zool. 39[1]:19–23). These specimens represent new country records for Ethiopia and Kenya and a new province record for Tanzania, and substantially extend range by over 1600 km N from holotype locality along Great Ruaha River, Tanzania, and suggests occurrence in additional areas in Kenya and Ethiopia. Presence in northwest Tanzania, as well as southwestern Kenya, suggests its distribution may be continuous along the shores of Lake Victoria.

Submitted by **BREDA M. ZIMKUS**, Department of Organismic and Evolutionary Biology, Harvard University, 26 Oxford Street, Museum of Comparative Zoology, Cambridge, Massachusetts 02138, USA; e-mail: bzimkus@oeb.harvard.edu.

PSEUDACRIS TRISERIATA (Upland Chorus Frog). USA: TENNESSEE: MADISON CO.: Field adjacent to a creek and woodland area along Old Pinson Road (35.513291°N, 88.760154°W;WGS 84). 23 February 2006. Mandy Messer. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18281, audio recording). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 25 pp.). GIBSON CO.: Woodland area adjacent to Rutherford Fork of the Obion River along Cades-Atwood Road (35.978074°N, 88.772482°W; WGS 84). 08 March 2006. Mandy Messer. (APSU 18257, audio recording). New county record (Redmond and Scott 1996, *op. cit*.). CARROLL CO.: Grassland area with temporary pools along Cutlip Road (35.931891°N, 92.146490°W; WGS 84). 08 March 2006. Mandy Messer (APSU 18248, audio recording). New county record (Redmond and Scott 1996, *op. cit*.).

Submitted by **MANDY MESSER, LAURIE BENNIE,** and **BRIAN P. BUTTERFIELD,** Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340, USA (e-mail: bbutterfield@fhu.edu).

TESTUDINES – TURTLES

CHELYDRA S. SERPENTINA (Eastern Snapping Turtle). USA: OHIO: CHAMPAIGN CO.: Urbana Township: Gravel quarry ponds in the Mad River Valley 1.5 km SW of Urbana (40.09651°N, 83.78784°W). 01 June 2007. Jeffrey G. Davis. Cincinnati Museum Center, Frederick and Amye Geier Research and Collections Center (CMC HP 469–471, photo vouchers). CLARK CO.: Moorefield Township, Prairie Road Fen (39.9971833°N, 83.7092667°W). 11 April 2006. Jeffrey G. Davis. (CMC HP 252, photo voucher). Both specimens verified by John W. Ferner. New county records (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contr. No. 10).

Submitted by **JEFFREY G. DAVIS**, Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA; e-mail: anura@fuse.net.

CLEMMYS GUTTATA (Spotted Turtle). USA: GEORGIA: JEFF DAVIS CO.: Found crossing Hwy. 107 between Snipesville and Coffee County line (31.76214°N, 82.82097°W). 26 February 2008. John B. Jensen and Dirk J. Stevenson. Verified by Elizabeth McGhee. Georgia Museum of Natural History (GMNH 50086, photographic voucher). First record for county (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia, Univ. Georgia Press, 575 pp.).

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame Conservation Section, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john_jensen@dnr.state.ga.us); and **DIRK J. STEVENSON**, 414 Club Drive, Hinesville, Georgia 31313, USA.

GRAPTEMYS GEOGRAPHICA (Northern Map Turtle). USA: OHIO: CLARK CO.: Springfield Township. Buck Creek below the CJ Brown Reservoir spillway (39.9502817°N, 83.7515883°W). 30 May 2006. Brian Menker. Verified by John W. Ferner. Cincinnati Museum Center (CMC Herp Photodocumentation Collection HP 254). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contr. No. 10, Columbus).

GRAPTEMYS GEOGRAPHICA (Northern Map Turtle). USA: ILLINOIS: Hancock Co.: Turtle was captured in a Mississippi River side channel between Eagle Island and the Illinois bank. Aproximate Mississippi River Mile 362 (40.37840°N, 091.39471°W). 03 June 2007. James T. Lamer, Sean E. Jenkins, Brian P. Jenkins, and Samuel W. Jenkins. INHS 20749. Verified by Chris Phillips. Specimen is a first county record and located at the Illinois Natural History Survey in Champaign/Urbana, Illinois (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.). Male turtle was captured in a Legler-style hoop net baited with Common Carp (*Cyprinus carpio*) carcasses. Turtle drowned during 24 h set. The following measurements were recorded: carapace length = 131 mm, carapace width = 95 mm, carapace height = 44 mm, plastron length = 107 mm, and mass = 236 g.

Submitted by **JAMES T. LAMER, SEAN E. JENKINS, BRIAN P. JENKINS, SAMUEL W. JENKINS,** Western Illinois University, 1 University Circle, Macomb, Illinois 61455, USA; **CHAD R. DOLAN** and **JOHN K. TUCKER,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

GRAPTEMYS PSEUDOGEOGRAPHICA (False Map Turtle). USA: ILLINOIS: Pike Co.: Turtle was dip-netted during a 300 m stretch of shoreline electro-fishing off of Denmark Island in the Mississippi River at River Mile 292 (39.54534°N, 91.13331457°W. 25 September 2006. Eric Ratcliff, Eric J. Gittinger, and Adam Carey. INHS 20222. Verified by Chris Phillips. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.). Male turtle was not immobilized during electrofishing, but was disoriented to allow capture.

Submitted by **JAMES T. LAMER,** Western Illinois University, 1 University Circle, Macomb, Illinois 61455, USA; **JOHN K. TUCKER, CHAD R. DOLAN, ERIC RATCLIFF, ERIC J. GITTINGER,** and **ADAM CAREY**, Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

GRAPTEMYS PSEUDOGEOGRAPHICA (False Map Turtle). USA: ILLINOIS: Tazewell Co.: Turtle was captured in a fyke net at Lower Powerton on Illinois River; mile 151 (40.55012°N, 89.68115°W). 03 October 2006. Kevin Irons, Melissa Smith, and Nerissa Michaels. INHS 20221. Verified by Chris Phillips, Illinois Natural History Survey. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.). Male turtle was captured in a standard fyke net set perpendicular to the shoreline, set for a duration of 24 h. This individual had a *kohni* morph head pattern. Carapace length = 90 mm.

Submitted by **JAMES T. LAMER,** Western Illinois University, 1 University Circle, Macomb, Illinois 61455, USA; **JOHN K. TUCKER, CHAD R. DOLAN,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA; **KEVIN IRONS, MELISSA SMITH,** and **NERISSA MICHAELS,** Illinois Natural History Survey, 704 North Shrader, Havana, Illinois 62644, USA.

GRAPTEMYS PSEUDOGEOGRAPHICA PSEUDOGEOGRAPHICA (False Map Turtle). USA: FLORIDA: Columbia Co.: O'Leno State Park, Santa Fe River, 1.2 km upstream from River Sink (29.917°N, 82.574875°W; datum WGS84). 1 October 2007. Anthony Lau and Gerald R. Johnston. UF 150678. Verified by Kenneth L. Krysko. New county record. Adult male (carapace length 131 mm, plastron length 122 mm, mass 320 g) captured in turtle hoop trap baited with canned sardines and frozen fish chum. This is the only *Graptemys* that we observed in over 400 trap nights conducted during freshwater turtle surveys in O'Leno State Park from May 2006 to November 2007. This non-native species is commonly sold in the pet trade, and given its role as an omnivore in the Mississippi River drainage (Ernst et al. 1994. Turtles of the US and Canada. Smithsonian Inst. Press, Washington. 578 pp.), the potential exists for establishment if additional releases of unwanted pets occur. This is the second record of a *G. p. pseudogeographica* in Florida (K. Krysko, pers. comm, UF 121459, Miami-Dade Co.).

Submitted by **ANTHONY LAU,** Department of Wildlife Ecology and Conservation, University of Florida, Gainesville, Florida 32611, USA (e-mail: alau0924@ufl.edu); and **GERALD R. JOHNSTON**, Department of Natural Sciences, Santa Fe Community College, Gainesville, Florida 32606, USA (e-mail: jerry.johnston@sfcc.edu).

MESOCLEMMYS PERPLEXA. BRAZIL: CEARÁ: Viçosa do Ceará (03.3655278°S; 41.1555833°W; 707 m elev.). 29 May 2007. D. Loebmann. Verified by M. Trefaut Rodrigues. Coleção de referência do Instituto Butantan, São Paulo, Brazil (CRIB 289). Previously reported only from type locality, Serra das Confusões National Park, Piauí state (09°16'S, 43°51'W) in Bour and Zaher (2005. Papeis Avulsos Zool. 45[24]:295–311). First state record extends the species distribution nearly 780 km N from the type locality.

Submitted by **DANIEL LOEBMANN**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Caixa Postal 199, CEP 13506-970, Rio Claro, São Paulo, Brazil; e-mail: contato@danielloebmann.com.

TERRAPENE C. CAROLINA (Eastern Box Turtle). USA: OHIO: Clark Co.: Moorefield Township. Crabill Homestead (39.9602612°N, 83.7338066°W). 21 May 2006. Brian Menker. Verified by John W. Ferner. Cincinnati Museum Center (CMC Herp Photodocumentation Collection HP 253). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contr. No. 10, Columbus).

Submitted by **BRIAN T. MENKER**, C. J. Brown Dam and Reservoir, 2630 Croft Road, Springfield, Ohio 45503, USA (e-mail: Brian.T.Menker@lrl02.usace.army.mil); and **JEFFREY G. DAVIS**, Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA (e-mail: anura@fuse.net).

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: FLORIDA: Columbia Co.: River Rise Preserve State Park, Santa

Fe River, 0.3 km downstream from River Rise (29.8716389°N, 82.5897917°W; datum WGS84). 13 June 2007. Gerald R. Johnston. UF 152605. Verified by Kenneth L. Krysko. New county record. Adult male (carapace length 160 mm, plastron length 148 mm, mass 680 g) captured by hand while snorkeling. A second specimen, UF 152604, was collected in Santa Fe River on 12 October 2007. This non-native turtle was previously observed in the Santa Fe River in 1987 (K. Enge, pers. comm.), 1991 (R. Ashton, pers. comm.), and 2006 (GRJ), but no voucher specimen was collected. Alachua County is the southernmost distribution where *T. s. scripta* naturally occurs (Thomas 2006. *In* P. A. Meylan [ed.]. Biology and Conservation of Florida Turtles. Chelonian Research Monog. 3:296–312). Morphological intermediates between native *T. s. scripta* and non-native *T. s. elegans* have been recorded from the Florida panhandle in Leon County (Aresco and Jackson 2006. Herpetol. Rev. 37:239–240), as well as the Santa Fe River (AL, YVK, and GRJ, pers. obs.), suggesting that *T. s. elegans* might be negatively affecting the existence of the native population.

KENTROPYX CALCARATA. BRAZIL, RIO GRANDE DO NORTE, Municipality of Parnamirim, Mata do Jiqui (05.9166667°S, 35.1833333°W). 03 February 2006. Pablo A. G. Sousa. Verified by Miguel T. U. Rodrigues. Coleção Herpetológica do Departamento de Botânica, Ecologia e Zoologia, Universidade Federal do Rio Grande do Norte, Natal. Rio Grande do Norte (CHBEZ 1316, 1487, 1488, 1566). The species was known from Venezuela to Maranhão State in Brazil. In the coastal areas of Brazil, it occurs from 19°S in Espírito Santo State to the Ambiental Preservation Area of Mamanguape in the Paraíba State and the Serra de Baturité, an isolated forested mountain range in the semiarid Caatingas in Ceará State. The Rio Grande do Norte State constitutes a gap between those two localities (Ávila-Pires 1995. Zool. Verh. Leid. 299:1–706; Gallagher and Dixon 1992. Boll. Mus. reg. Sci. nat. Hist. 10[1]:125–171; Vanzolini 1988. Proc. Work. Neotropical Distribution Patterns, pp. 317–342; Borges-Nojosa and Caramaschi 2003. Ecol. Cons. Caat. v. 01, pp. 489–540). First state record, extends the range 450 km E and 225 km N from the areas of Ceará and Paraíba states, respectively, and fills the gap in the distribution of the species.

Submitted by **PABLO A. G. SOUSA** and **ELIZA M. X. FREIRE**, Laboratório de Herpetologia. Departamento de Botânica, Ecologia e Zoologia, Centro de Biociências, Universidade Federal do Rio grande do Norte, Campus Universitário, Lagoa Nova, CEP 59072-970, Natal, Rio Grande do Norte, Brazil.

LEIOLEPIS TRIPLOIDA (Malaysian Butterfly Lizard). MALAYSIA: KEDAH: Kampung Wang Perah (6.3645333°N, 100.46005°E). 26 October 2008. M. S. Shahrul Anuar. La Sierra University Herpetological Collection (LSUHC 8734). Kuala Nerang (18.9 km SW of Kampung Wang Perah). 10 March 1930 and 15 March 1930. G. Hope Sworder. Raffles Museum of Biodiversity Research, National University of Singapore, Zoological Reference Collection (ZRC 2.961 and ZRC 2.962–63, respectively). Pokok Sena (22.2 km S of Kampung Wang Perah). 16 February 1930. G. Hope Sworder. ZRC 2.964. PENANG: Mengkuang Dam (5.3897833°N, 100.5025833°E). 25 October 2008. M. A. Muin. LSUHC 8715. All specimens verified by J. L. Grismer. Type locality given as "Malayisch-thailändisches Grenzgebiet auf der Malayischen Halbinsel" (= Malaysia-Thailand border of the Malay Peninsula; Peters 1970. Zool. Jb. Syst. Bd. 98:11–130), which could conceivably mean any place along the ca. 400 km border. A locality was subsequently illustrated on distribution maps (Darevsky and Kupriyanova 1993. Herpetozoa

6:3–20; Aranyavalai et al. 2004. Nat. Hist. J. Chulalongkorn Univ. 4:15–19), showing it to be near the Thai border in northern Kedah, Malaysia at the town of Baling (5.6752333°N, 100.9170167°N). We visited Baling on 26 October 2008 but residents indicated this species was not present and directed us to Kampung Bandar (5.7500333°N, 100.8808333°E), 9.2 km to the NW, where we found five specimens (LSUHC 8710–14). In reference to Kampung Bandar, the presence of this species at Kuala Nerang, 68 km to the NNW; at Kampung Wang Perah, 84 km to the NW; and at Pokok Sena, 68 km to the WNW, extends the distribution of this species along the Malaysia-Thailand border to the northwest. Its presence at the Mengkuak Dam in Seberang Perai, 57.8 km to the SW extends its distribution towards the west coast. These widely distributed localities suggest *L. triploida* ranges throughout most of Kedah, rather than being restricted to the border of Malaysia and Thailand.

CROTALUS ATROX (Western Diamondback Rattlesnake). USA: TEXAS: Caldwell Co.: Plumb Creek Farm off Farm Road 672, 3 miles NE of Lockhart (29.8983833°N, 97.6494667°W). 01 February 2006. Verified by J. R. Dixon, Texas A&M University, Texas Cooperative Wildlife Collection. TCWC 90669. New county record (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas. 148 pp.). A total of 3 adult females, 1 adult male, and 1 juvenile female *Crotalus atrox* were collected from an old farm shed under a wood pile. These are the first reported specimens from within Caldwell County. Each individual was measured, weighed, and had a blood sample (MF-19885,19914–19917) and digital photo taken. The specimens ranged in size from SVL length of 38–96 cm and tail length of 22–71 mm. One individual was retained as a specimen voucher and preserved and accessioned into the Texas Cooperative Wildlife Collection (TCWC 90669).

ECHINANTHERA AFFINIS (Günther's Forest Snake). BRAZIL: CEARÁ: Ubajara (03.8404722°S, 40.9076389°W; 896 m elev.). 02 Jul 2007. D. Loebmann. Ubajara (03.8475278°S, 40.8890833°W; 884 m elev.). 05 Sep 2007. H. Klein. Coleção Instituto Butantan, São Paulo, Brazil (IBSP 76363–76364). Verified by M. Trefaut Rodrigues. The species was known from the states of Rio Grande do Sul, Santa Catarina, Paraná, São Paulo, Rio de Janeiro, Minas Gerais, Espírito Santo, and Bahia (Di-Bernardo and De Lema 1988. Acta Biol. Leopol. 10[2]:223–252; Argôlo 1998. Herpetol. Rev. 29:176). These new records represent an isolated population in the rain forests of Ibiapaba's plateau and also are the first records for Ceará state. Extends distribution ca. 1230 km N from Vitória da Conquista, Bahia state, Brazil (Argôlo, *op. cit*.).

Submitted by **DANIEL LOEBMANN**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Caixa Postal 199, CEP 13506-970, Rio Claro, São Paulo, Brazil; e-mail: contato@danielloebmann.com.

LAMPROPELTIS CALLIGASTER OCCIPITOLINEATA (South Florida Mole Kingsnake). USA: FLORIDA: Charlotte Co.: 4.4 km NE of intersection of Graham Road and County Road 74 (26.9711389°N, 81.6781667°W). 07 March 2008. Robert A. O'Horo. Adult male (825 mm SVL) collected alive on an unpaved road at 1215 h in an area of dry prairie habitat surrounded by agricultural fields. Verified by Kenneth L. Krysko. Florida Museum of Natural History photo voucher (UF 152523). New county record. Extends range ca. 22 km SE of the nearest record from DeSoto Co. (UF 152370). Vouchers of this subspecies also exist from Brevard and Okeechobee counties (Layne et al. 1986. Florida Sci. 49:171–175), and we have reports unsupported by vouchers from nearby Glades, Indian River, and Osceola counties. A purported specimen (UMMZ 77481) collected from Leesburg, Lake Co. (Layne et al., *op. cit*.), was a misidentified *Pantherophis guttatus* (G. Schneider, pers. comm.).

Submitted by **ROBERT A. O'HORO**, Florida Fish and Wildlife Conservation Commission, 2423 Edwards Drive, Ft. Myers, Florida 33901, USA (e-mail: robert.ohoro@myfwc.com); and **KEVIN M. LAMPROPELTIS TRIANGULUM ARCIFERA (Jalisco Milksnake). MÉXICO: MÉXICO: Municipality of Tejupilco, (18.51314°N, 100.25347°W; NAD27 México), 1800 m elev. 14 April 2001. Octavio Vilchis. Verified by Óscar Sánchez. IBH 15741. First record for Tejupilco and a 49.5 km range extension W from the closest known locality at Sultepequito, México (Casas and Aguilar 1998. Biol. Soc. Herpetol. Mex. 8:22–24). The record also fills the distributional gap on the southcentral portion of the Mexican Plateau that was depicted by Williams (1988. Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum.* 2nd revised ed. Milwaukee Pub. Mus., Milwaukee, 176 pp.). The snake was found in pine-oak forest (*Quercus elliptica* and *Pinus oocarpa*).

Submitted by **FELIPE RODRÍGUEZ-ROMERO, OCTAVIO MONROY-VILCHIS,** and **OSWALDO HERNÁNDEZ-GALLEGOS,** Facultad de Ciencias, Centro de Investigación en Recursos Bióticos–CIRB, Universidad Autónoma del Estado de México, Instituto Literario # 100, 50000, Toluca, Estado de México, México (e-mail: fjrr@uaemex.mx).

LAMPROPELTIS TRIANGULUM SYSPILA (Red Milksnake). USA: ARKANSAS: Pulaski Co.: 34.791535°N, 92.487877°W; WGS84, 195 m elev. 29 March 2007. UALR HPC 0001. 34.475527°N, 92.342141°W, WGS84, 165 m elev. 03 April 2007. UALR HPC 0002. Verified by M. V. Plummer. New county records (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville, Arkansas. 421 pp.).

Allocation to *L. t. syspila* based upon features of distinctive coloration and markings (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). UALR HPC 0001 was captured under a piece of discarded carpet within a utility right-of-way adjacent to a mixed hardwood woodlot. It is currently housed as a live specimen within the University of Arkansas at Little Rock Biology Department and will be preserved as an alcohol specimen upon its death. The adjacent area from which UALR HPC 0001 was captured is currently undergoing development as a gated housing community. Urban sprawl in Little Rock might pose a threat to the habitat for *L.t. syspila* at this particular locality.

UALR HPC 0002 was captured at a private residence within a mixed hardwood forest and was photographed and released at the capture site. An additional individual was sighted 15 August 2007 at the same location as UALR HPC 0002.

Submitted by **DARRELL R. HEATH**, **DAVID W. CLARK,** and **KRYSTIAN A. SAMEK**, Department of Biology, University of Arkansas at Little Rock, Little Rock, Arkansas 72204, USA (e-mail: drheath@ualr.edu).

MICRURUS TENER (Texas Coralsnake). MÉXICO: HIDALGO: Municipality of Metztitlán, San Pablo Tetlapayac, Reserva de la Biosfera Barranca de Metztitlán (20.38311°N, 98.55400°W; WGS849), 993 m elev. 23 March 2007. V. D. Vite-Silva and U. Hernández-Salina. Verified by Adrian Leyte-Manrique. Herpetology collection, Laboratorio Ecología de Poblaciones, Centro de Investigaciones Biológicas, Universidad Autónoma del Estado de Hidalgo (VDVS-UAEH-0042). First record for the municipality and a range extension of 51 km S of record in the Municipality of Tlanchinol (Mendoza-Quijano et al. 2006. Publicación Especial de la Sociedad Herpetológica Mexicana [3]:99–109). The snake was found in tropical dry forest. Fieldwork was funded by SEP-PROMEP-1103.5/03/1130, Projects PIFI-PROMEP 3.3. 2007, CONACYT-S 52552-Q, and CONACYT-43761.

NERODIA ERYTHROGASTER (Plain-bellied Watersnake). USA: ILLINOIS: Henderson Co.: Snake was captured as it basked on riprap stone embankment alongside lake at Crystal Lake Gun Club, Gulfport, Illinois (40.83540°N, 091.06121°W). 08 June 2007. James T. Lamer and Sean E. Jenkins. Illinois Natural History Survey in Champaign/Urbana, Illinois (INHS 20745). Verified by Chris Phillips. First county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.)

Submitted by **JAMES T. LAMER, SEAN E. JENKINS,** Western Illinois University, 1 University Circle, Macomb, Illinois 61455, USA; **JOHN K. TUCKER** and **CHAD R. DOLAN,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

NERODIA ERYTHROGASTER ERYTHROGASTER (Red-bellied Watersnake). USA: VIRGINIA: Henrico Co.: 11.4 km ESE Sandston, Whiteoak Swamp Creek (37.4683333°N, 77.2086111°W). 10 August 2004. H. Lacy. Verified by William M. Palmer. North Carolina State Museum of Natural Sciences (NCSM 73872). New county record. Extends range ca. 59 km NNE and ca. 68 km WNW of nearest records in Sussex and York counties, respectively (Mitchell 1994. The Reptiles of Virginia. Smithsonian Institution Press, Washington, DC. xv + 352 pp.).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Research Laboratory, 4301 Reedy Creek Road, Raleigh, North Carolina 27607, USA (e-mail: jeff.beane@ncmail.net); and **THOMAS J. THORP**, Three Lakes Nature Center and Aquarium, 400 Sausiluta Drive, Richmond, Virginia 23227, USA (e-mail: tho56@co.henrico.va.us).

OPHEODRYS VERNALIS (Smooth Greensnake). USA: ILLINOIS: DeKalb Co.: Kishwaukee River State Fish and Wildlife Area in Kirkland (42.09431°N, 88.86872°W). A live female individual (SVL 217 mm) was captured under cover boards on 20 April 2007. The individual was photographed and released as part of an ongoing herpetological survey within the park (verified and vouchered via photograph by Chris Phillips at the Illinois Natural History Survey, voucher number: INHS 2008-3). This is the second verified sighting of this species within this county, the first sighting was published as a county record (Walley 1977. Herpetol. Rev. 8:125). Walley's sighting occurred in the southern portion of the county, and this latest record documents that this species persists in the far northern portion of the county and potentially countywide. This capture extends the known range of this species 53.7 km NW, and is 123 km NW from the only viable population of this species in northern Illinois known to us.

Submitted by **JACE W. ROBINSON** and **JESSE W. RAY**, Department of Biological Sciences, Northern Illinois University, DeKalb, Illinois 60115, USA; e-mail: z052078@wpo.cso.niu.edu.

OXYRHOPUS GUIBEI. BRAZIL: RIO DE JANEIRO: Municipality of Resende: Serrinha do Alambari (22.3833333°S, 44.5333333°W, ca. 700 m elev.). 02 September 2005. U. Caramaschi and H. Niemeyer. Museu Nacional, Rio de Janeiro, RJ, Brazil (MNRJ 13737, 13738). Resende: District of Visconde de Mauá (22.3333333°S, 44.5333333°W, ca. 1000 m elev.). 02 January 2006. M. A. S. Alves. Museu Nacional (MNRJ 14627). Municipality of Barra Mansa (22.55°S, 44.1666667°W, ca. 450 elev.). 14 March 2006. A. Chiessi. Museu Nacional (MNRJ 15603). All localities in the Atlantic Forest biome. Verified by R. Fernandes. Species was previously known from Brazilian states of Minas Gerais, São Paulo, Goiás, Mato Grosso, Mato Grosso do Sul, Paraná, Bahia, and Alagoas, and the Distrito Federal; Bolivia, Paraguay, and northeastern Argentina (Argôlo 2004. As Serpentes dos Cacauais do Sudeste da Bahia. Editora da UESC, Ilhéus, 259 pp.; França and Araújo 2006. S. Amer. J. Herpetol. 1[1]:25–36; Freire 1999. Herpetol. Rev. 30:55; Zaher and Caramaschi 1992. Bull. Mus. Natl. Hist. Nat. 14[3–4]:805–827). First state records, the record from Barra Mansa extends known distribution ca. 230 km NE from the closest previous record (Municpality of Guarulhos, São Paulo; Zaher and Caramaschi, *op. cit*.) and ca. 320 km S from the closest record in Minas Gerais (Municipality of Lagoa Santa; Zaher and Caramaschi, *op. cit*.).

Submitted by **ADRIANO LIMA SILVEIRA**, Setor de Herpetologia, Departamento de Vertebrados, Museu Nacional / Universidade Federal do Rio de Janeiro, Quinta da Boa Vista, São Cristóvão, CEP 20940-040, Rio de Janeiro, RJ, Brazil; e-mail: biosilveira@yahoo.com.br.

OXYRHOPUS RHOMBIFER BACHMANNI (False Coralsnake). ARGENTINA: CHUBUT: Telsen Department: Estancia Maria de las Nieves, 15–20 km NW Sierra Chata (42.53124°S, 65.6369°W; WGS84) by Ruta Provincial 4. September 2007. V. Marquez and H. Vallejos. Verified by C. H. F. Perez. Museo Argentino de Ciencias Naturales Bernardino Rivadavia, Buenos Aires, Argentina (MACN 39042). First province record, southermost record for the species in Argentina, extends the known distribution 600 km (airline) S from previous and southernmost vouchered citation (Avila and Morando 1999. Herpetol. Rev. 30:114). Previous records in Argentina are for Catamarca, Córdoba, La Pampa, La Rioja, Mendoza, Río Negro, San Juan, San Luis, Santiago del Estero, and Tucumán (Giraudo and Scrocchi 2002. Smithson. Herpetol. Infor. Serv. 132:1–53).

Nat. Hist.17:1–13; Freitas 1999. Serpentes da Bahia e do Brasil – Suas Características e Hábitos. Ed. Dall. 77 pp.). First state record extends range ca. 700 km N from the limit of coastal region of Bahia.

Submitted by **PABLO A. G. SOUSA** and **ELIZA M. X. FREIRE**, Laboratório de Herpetologia, Departamento de Botânica, Ecologia e Zoologia, Centro de Biociências, Universidade Federal do Rio Grande do Norte, Campus Universitário, Lagoa Nova, CEP 59072-970, Natal, Rio Grande do Norte, Brazil.

PHYLLORHYNCHUS BROWNI (Saddled Leaf-nosed Snake). USA: ARIZONA: PINAL CO.: East side of Goldmine Mountains (33.191596°N, 111.616985°W) 461 m elev. 17 May 2004. Justin P. Pullins and Tanzy D. Pullins. University of Arizona Museum (photo voucher; UAZ 56666-PSV). Verified by George Bradley. This record fills a gap in the known distribution of this species. Specimen found ca. 28 km NW of a series of specimens collected near Florence, Arizona and ca. 90 km ENE of the nearest specimen (ASU 33136) to the west (A. T. Holycross, pers. comm; Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix, Arizona. 150 pp.).

Submitted by **JUSTIN P. PULLINS**, Arizona State University Polytechnic Campus, 7001 E. Williams Field Road, Mesa, Arizona 85212, USA.

SISTRURUS MILIARIUS STRECKERI (Western Pigmy Rattlesnake). USA: ARKANSAS: SEARCY CO.: Off AR 14, ca. 2 km down Ramblewood Trail by private residence. 21 June 2007. J. S. Hicks, M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 30742). First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MATTHEW B. CONNIOR** and **IDUN GUENTHER**, Department of Biological Sciences, Arkansas State University, P.O. Box 599, State University, Arkansas 72467, USA (e-mail: matthew.connior@smail.astate.edu).

STORERIA DEKAYI (DeKay's Brown Snake). USA: OHIO: BROWN CO.: Pleasant Township: White Oak Creek at Old State Route 125 bridge, 1.0 km W of Georgetown (38.86546°N, 83.86546°W). 14 June 2007. Jeffrey G. Davis, John W. Ferner, and Paul J. Krusling. Verified by Jason Folt. Voucher specimen deposited at Cincinnati Museum Center, Ferderick and Amye Geier Research and Collections Center (CMC 10919). New county record (Wynn and Moody 2006. Ohio Turtle, Lizard, and Snake Atlas. Ohio Biol. Surv. Misc. Contr. No. 10).

Submitted by **JEFFREY G. DAVIS** (e-mail: anura@fuse.net), and **PAUL J. KRUSLING** (e-mail: pkrusling@fuse.net), Cincinnati Museum Center – Fredrick and Amye Geier Research and Collections Center, 1301 Western Avenue, Cincinnati, Ohio 45203-1130, USA; and **JOHN W. FERNER**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA (e-mail: JohnFerner@Thomasmore.edu).

THAMNOPHIS EQUES (Mexican Gartersnake). USA: ARIZONA: GILA CO.: Tonto Creek, between Gisela and Punkin Center. On 23 August 1995 at 2200 h, we found a *Thamnophis eques* (UAZ 50327) dead on State Route 188, ca. 3 km N of Punkin Center at 720 m elev. The specimen measured 310 mm SVL and 91 mm tail. This specimen is the first record of *T. eques* from the Tonto Creek watershed, and fills a substantial gap in the distribution of the species in the Gila River watershed between voucher specimens from Maricopa and Yavapai counties ca. 80 airline km to the west and records from the Black River and its tributaries ca. 110 airline km to the east.

On 14 July 2004, 18–19 August 2004, and 20–24 June 2005 we spent 165 person-hours searching along the banks of Tonto Creek between Gisela and "The Box" (ca. 3 km of stream at 870 m elev.); a location approximately 26 river km upstream of the collection locality of UAZ 50327 (Holycross et al. 2006. Surveys for *Thamnophis eques* and *Thamnophis rufipunctatus* in the Gila Watershed of Arizona and New Mexico. Report to Arizona Game and Fish Department. 105 pp.). We also deployed 32 Gee's "minnow traps" along the banks on 18–19 August 2004 (704 trap-hours) and 210 traps from 20–24 June 2005 (19,740 trap-hours). One adult female *T. eques* (ASU 34844) was trapped. From 20–23 June 2005 we captured 14 neonates (163–216 mm SVL, mean = 184; 2.5–6.0 g, mean = 3.8) and one adult female (820 mm SVL, 170 g) by hand. A second adult female (650 mm SVL, 135 g) was trapped twice.

Non-native predators (Bullfrogs, *Lithobates catesbeianus;* crayfish, *Orconectes virilis;* catfish, *Ameirus* spp.; bass, *Micropterus* spp.) were abundant, whereas a native prey species (Lowland Leopard Frog, *Lithobates yavapaiensis*) was not found. Only relatively large adult females and neonates were captured in 2004 and 2005. Low catch per unit effort (adults), absence of intermediate age classes, and presence of non-native predators suggest a low density population and raise the possibility that recruitment may be

declining in this recently discovered population.

TYPHLOPS BRONGERSMIANUS (Brongersma's Worm Snake). BRAZIL: CEARÁ: Ubajara (03.8619444°S; 40.9172222°W; 834 m elev.). 06 April 2007. D. Loebmann. Coleção Instituto Butantan, São Paulo, Brazil (IBSP 76365). Verified by M. T. Rodrigues. Species widely distributed with recognized records from Trinidad, Peru, Ecuador, Colombia, Venezuela, Guiana, French Guiana, Suriname, Brazil, Bolivia, Paraguay, and Argentina (Dixon and Hendricks 1979. Zool. Verh. Leiden. 173:1–39; McDiarmid et al. 1999. Snake Species of the World: A Taxonomic and Geographic Reference, Vol. 1. Herpetologists' League, Washington, DC, xii + 511 pp.). First state record, extends the distribution previously known as follows: ca. 760 km NW from the João Pessoa city, Paraíba state, Brazil (Santana et al. 2008. Biotemas. 21[1]:75–84); ca. 700 km N from the ecological station of Uruçui-Una, Piauí state, Brazil and ca. 700 km NE from the Balsas city, Maranhão state, Brazil (Barreto 2007. Cerrado Norte do Brasil = North Cerrado of Brazil. União Sul Americana de Estudos da Biodiversidade, Pelotas, Brazil, 378 pp.); also ca. 620 km E from the Junco do Maranhão city, state of Maranhão, Brazil (Cunha and Nascimento 1993. Bol. Mus. Para. Emílio Goeldi, sér. Zool. 9[1]:1–191).

Noteworthy Geographic Distribution Records for Colubrid Snakes from the Arkansas Valley Ecoregion of Westcentral Arkansas, USA

HENRY W. ROBISON
Department of Biology, Southern Arkansas University
Magnolia, Arkansas 71754, USA
e-mail: hwrobison@saumag.edu

and
CHRIS T. McALLISTER
Department of Physical and Life Sciences, Chadron State College
Chadron, Nebraska 69337, USA
e-mail: drctmcallister@aol.com

Thirty-eight species and subspecies of colubrid snakes occur in Arkansas (Trauth et al. 2004). Since the compilation of Trauth et al. (*op. cit.*), numerous investigators have recently reported new county records for colubrids in various parts of the state (Engelbert and Patrick 2007; Engelbert et al. 2007; Howey and Dinkelacker 2007; Plummer and McKenzie 2007; Robison and McAllister 2007). Between December 2005 and September 2006, additional geographic (new county) records for eight species of colubrids were collected from Johnson, Pope, and Yell counties of the Arkansas Valley of west-central Arkansas. Township, section, and range are provided for each locality. Specimens were verified by S. E. Trauth and vouchers are deposited in the Arkansas State University Herpetological Museum (ASUMZ), State University, Arkansas. Current common and scientific names follow Crother et al. (2000) except where noted.

Colubrinae

Lampropeltis calligaster calligaster (Prairie Kingsnake). JOHNSON CO.: Clarksville, Clark Road (Sec. 1, T9N, R23W). 05 July 2005. Joe Kremers. ASUMZ 30796. New county record that partially fills a distributional gap among Franklin and Newton counties and near a previous record from Madison County (Roberts et al. 2005). Juvenile specimen.

Lampropeltis getula holbrooki (Speckled Kingsnake). JOHNSON CO.: Clarksville, Clark Road (Sec. 1, T9N, R23W). 05 July 2005. Joe Kremers. ASUMZ 30794. New county record that fills a hiatus in the northwestern Arkansas River Valley among Franklin, Logan, and Pope counties. Juvenile Specimen. This snake is one of the most common colubrids of the state, now being reported from 73 of 75 (97%) counties.

Opheodrys aestivus (Rough Greensnake). YELL CO.: Mt. George (Sec. 4, T5N, R21W). 08 June 2006. Joe Kremers. ASUMZ 30800. New county record partially filling a hiatus in the southern Arkansas River Valley among Perry and Scott counties.

Natricinae

Nerodia rhombifer rhombifer (Northern Diamond-backed Watersnake). JOHNSON CO.: Clarksville, Clark Road (Sec. 1, T9N, R23W). 27 December 2005. Joe Kremers. ASUMZ 30793. New county record and juvenile specimen.

Storeria dekayi wrightorum (Midland Brownsnake). JOHNSON CO.: Clarksville, Clark Road (Sec. 1, T9N, R23W). 11 September 2006. Joe Kremers. ASUMZ 30797. New county record.

Storeria occipitomaculata occipitomacula (Northern Red-bellied Snake). POPE CO.: 1.6 km N London (Sec. 17, T8N, R21W). 15 September 2006. Joe Kremers. ASUMZ 30799. New county record among Johnson, Logan, and Pope counties. This snake is uncommon in the state although it is widely distributed among all ecoregions (Trauth et al., *op. cit.*).

Thamnophis proximus proximus (Orange-striped Ribbonsnake). JOHNSON CO.: Clarksville, Clark Road (Sec. 1, T9N, R23W). 27 December 2005. Joe Kremers. ASUMZ 30795. New county record.

Thamnophis sirtalis sirtalis (Eastern Gartersnake). POPE CO.: 3.2 km S Dover (Sec. 3, T8N, R20W). 15 September 2006. Joe Kremers. ASUMZ 30798. New county record partially filling a hiatus among Conway and Johnson counties.

Acknowledgments.—We especially want to thank Joe Kremers (Clarksville, Arkansas) for providing these specimens. We also thank S. E. Trauth (ASUMZ) for curatorial assistance and specimen verification. Specimens were collected under the authority of Arkansas Scientific Collecting Permits issued to HWR by the Arkansas Game and Fish Commission.

e-mail: midorcas@davidson.edu

Knowledge of reptile and amphibian distribution patterns is essential for the development of effective conservation strategies (Tuberville et al. 2005), especially in regions that are becoming increasingly urbanized. Here we report new county records of reptiles and amphibians from the rapidly growing Charlotte-metropolitan area in the western Piedmont of North Carolina. The following records were collected from 2003 to 2007 by members of the Davidson College Herpetology Laboratory. All coordinates listed use NAD83/WGS84 datum and were recorded using a Garmin® hand-held geographic positioning system or online mapping software (www.carolinaherpatlas.org/utmfinder/). New distribution records were verified by Jeffrey C. Beane and/or Alvin L. Braswell at the North Carolina State Museum of Natural Sciences (NCSM) and were based on Palmer and Braswell (1995) or Braswell (1996). All specimens or photo vouchers are housed at NCSM.

Caudata– Salamanders

Eurycea guttolineata (Three-lined Salamander). LINCOLN CO.: 0.8 km ENE of intersection of Woodcock trail and Killian Farm Rd (35.4143°N, 80.9676°W). 03 May 2007. Steven J. Price and Kristen K. Cecala. NCSM 73513. New county record.

Gyrinophilus porphyriticus (Spring Salamander). MECKLENBURG CO.: Stephen's Road Nature Preserve, ca. 1.5 km SW of intersection of Stephen's Rd and Beaties Ford Rd (35.4013°N, 80.9448°W). 18 April 2007. Steven J. Price. NCSM 73512. New county record.

Pseudotriton ruber (Red Salamander). IREDELL CO.: Davidson College Ecological Preserve, ca. 1.0 km E of intersection of Dunmurry Rd and State Hwy 115 (35.5104°N, 80.8278°W). 1 May 2004. Yurii V. Kornilev and William J. Johnson. NCSM photo DC-308. New county record.

Anura – Frogs

Hyla cinerea (Green Treefrog). CABARRUS CO.: 0.9 km NW of intersection of Cox Mill Rd and Christenbury Rd (35.3853°N,

80.7372°W). 02 November 2005. Steven J. Price and Yurii V. Kornilev. NCSM 72672. New county record.

Testudines – Turtles

Chelydra serpentina (Snapping Turtle). IREDELL CO.: Five Mile Branch Stream Restoration Site, 0.3 km SSE of intersection of River Hill Rd and Swann Rd (35.4143°N, 80.9676°W). 23 February 2007. Leigh Anne Harden and Wesley M. Anderson. NCSM photo DC-305. Observation reported by Palmer and Braswell (1995). First photo voucher from county.

Chrysemys picta (Painted Turtle). IREDELL CO.: Five Mile Branch Stream Restoration Site, ca. 1.0 km ESE of intersection of River Hill Rd and Swann Rd (35.8462°N, 80.7680°W). 2 July 2007. Leigh Anne Harden and Steven J. Price. NCSM photo DC-306. New county record.

Kinosternon subrubrum (Eastern Mud Turtle). IREDELL CO.: ca. 0.7 km NE of intersection of Midway Lake Rd and Beracah Place (35.5294°N, 80.8210°W). 24 April 2006. Shannon E. Pittman. NCSM 72703. Observation reported by Palmer and Braswell (1995). First specimen from county.

Sternotherus odoratus (Eastern Musk Turtle). CABARRUS CO.: 0.3 km NE of intersection of Blackwelder Rd and Roberta Rd (35.3506°N, 80.6324°W). 8 July 2005. Elisabeth L. Failey. NCSM 72705. New county record.

Squamata – Snakes

Lampropeltis getula (Common Kingsnake). CABARRUS CO.: Morrison Rd, 0.3 km E of intersection with Pioneer Mill Rd (35.2612°N, 80.5870°W). 24 April 2006. Steven J. Price and Kristen K. Cecala. NCSM 72677. Observation reported by Palmer and Braswell (1995). First specimen from county.

Storeria dekayi (Dekay's Brownsnake). IREDELL CO.: Five Mile Branch Stream Restoration Site, ca. 2.0 km ESE of intersection of River Hill Rd and Swann Rd (35.8510°N, 80.7535°W). 29 October 2006. Leigh Anne Harden and Wesley M. Anderson. NCSM photo DC-307. Observation reported by Palmer and Braswell (1995). First photo voucher from county.

Storeria occipitomaculata (Red-bellied Snake). IREDELL CO.: Davidson College Ecological Preserve, ca. 1.0 km ENE of intersection of Dunmurry Rd and State Hwy 115 (35.5097°N, 80.8305°W). 30 April 2003. Kristine L. Grayson. NCSM 73525. Observation reported by Palmer and Braswell (1995). First specimen from county.

New County Records of Reptiles and Amphibians from East Texas

JESSICA L. COLEMAN
and
JAKE A. PRUETT
Department of Biology, University of Texas at Tyler
Tyler, Texas 75799, USA
e-mail (JLC): jessicoleman@gmail.com

Here we report several new reptile and amphibian county records for the state of Texas. Despite the number of researchers working throughout the state, many common species have not been documented (Dixon 2000). During the summer and fall of 2007, we surveyed various east Texas counties to document unrecorded reptile and amphibian species. The nomenclature used is in accordance with Crother et al. (2000) and identifications were verified by C. J. Franklin. Voucher specimens are deposited at the Amphibian and Reptile Diversity Research Center (UTA), University of Texas at Arlington, Arlington, Texas and the University of Texas at Tyler, Tyler, Texas. All specimens were collected under the authorization of the Texas Parks and Wildlife Department (permit no. SPF-0806-713).

Anura – Frogs

Anaxyrus americanus charlesmithi (=Bufo americanus charlesmithi) (Dwarf American Toad). CAMP CO.: Approximately 0.48 km N from the intersection of County Rd 2319 and Farm Rd 1520 (33.06639°N, 095.02459°W; NAD27), 105 m elev. 14 September 2007. Jake A. Pruett and Jessica L. Coleman. UTA A-58017. Found in an oak-hickory woodland near Bob Sandlin Lake with at least 3 other *A. a. charlesmithi*, as well as several *Acris crepitans* and *Rana sphenocephala*.

Testudines – Turtles

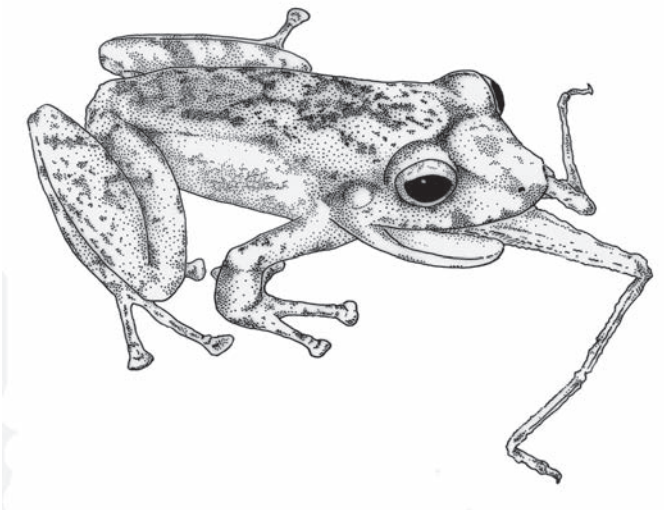
Chelydra serpentina (Common Snapping Turtle). LAMAR CO.: Camp Maxey, Texas Army National Guard training site. Approximately 16.1 km N of Paris, Texas on Hwy 271 (33.79811°N, 095.567703°W; NAD27), 167 m elev. 24 July 2007. Jessica L. Coleman. UTA R-55473. Shell was found on shore of a small pond among sedges and grass species. Holes were present in the carapace resembling punctures of small mammal incisors; however, predation could not be determined.

Graptemys pseudogeographica kohnii (Mississippi Map Turtle). WOOD CO.: Texas Parks and Wildlife Department Old Sabine Bottom Wildlife Management Area. Approximately 12.8 km N of Lindale, Texas on County Rd. 4106 (32.60190°N, 095.32918°W; NAD27), 85 m elev. 15 May 2007. Jessica L. Coleman. UTADC 1094–95. Adult male photographed basking (1125 h) in a 1.5 km section of the Sabine River with approximately nine *G. p. kohnii* and five other species of turtles (Emydidae). In this section of river a total of 116 individual turtles of various species were observed basking that day.

Sternotherus carinatus (Razorback Musk Turtle). TITUS CO.: Bob Sandlin State Park. Approximately 19.3 km SW of Mt. Pleasant, Texas (33.06188°N, 095.06506°W; NAD27), 127 m elev. 14 September 2007. Jake A. Pruett and Jessica L. Coleman. UTA R-55474. Shell was found within 2 m of the north shoreline of Bob Sandlin Lake in oak woodland habitat.

Trachemys scripta elegans (Red-eared Slider). UPSHUR CO.: Approximately 0.2 km W from the intersection of West Lake Drive and Woodbine Drive (32.54222°N, 94.94694°W; NAD27). 15 September 2005. Jessica L. Coleman. University of Texas at Arlington (UTADC 1099). A female was found crossing West Lake Drive, ca. 50 m S of Gladewater Lake in a residential area.

Squamata – Snakes



Regina grahamii (Grahams Crayfish Snake). SMITH CO.: Texas Parks and Wildlife Department Old Sabine Bottom Wildlife Management Area. Approximately 12.8 km N of Lindale, Texas on County Rd. 4106 (32.58589°N, 095.35719°W; NAD27), 129 m elev. 20 May 2007. Jake A. Pruett. University of Texas at Tyler (UT Tyler 516). Snake captured in minnow trap placed at the land/water interface of an oxbow lake. An unidentified species of crayfish (determined by palpation) had been consumed by the snake, but it could not be determined if predation occurred after entering the trap.

Acknowledgments.—We thank R. C. Jadin, C. J. Franklin, and J. A. Campbell for depositing specimens and images at the Amphibian and Reptile Diversity Research Center. We additionally thank R. C. Jadin and J. Placyk for their constructive criticism.

e-mail: aaron.bauer@villanova.edu

Most Western and Central European countries have recently compiled national atlases of their herpetofaunas. The Italian effort to map the national herpetofauna has been noteworthy for its generation of many regional and provincial atlases, as well as a preliminary atlas (Societas Herpetologica Italica, 1996), prior to the publication of the definitive work. The result is a spectacular, highly readable and highly useful volume. The book provides a dual Italian/English text, making it accessible to a broad range of readers.

The book begins with an engaging history of Italian herpetology by Violani and Barbagli. This well illustrated chapter, with portraits of Italian herpetologists and illustrations and title pages from their works covers the gamut from the earliest forays into herpetology to the great collectors of the 19th and 20th centuries. Among the more illustrious names included are Aldrovandi, Redi, Malpighi, Vallisneri, Spallanzani, Rafinesque, Rusconi, Panizza, Gené, Peracca, Camerano, Lessona, Bonaparte, Jan, Scortecci, and Doria.

Chapter two, by Massimo Delphino, summarizes the fossil record of the living species. The Miocene to Holocene record is surprisingly representative of the living diversity, with 38 taxa represented plus another 11 genera that are extant, but no longer occur in Italy (e.g., *Tomistoma*, *Agama*, *Varanus*, *Eryx*). This chapter is illustrated by drawings of selected fossils and small photographs of the corresponding living taxa.

Chapter three overviews the genesis of the atlas project and relevant data gathering. The project was begun in 1994 and resulted, only two years later, in the publication of the provisional atlas (Societas Herpetologica Italica, 1996). Over the intervening years many regional and provincial atlases were published. In all over 70,000 data points were plotted on 3382 10 × 10 km UTM coordinates. These were gathered by more than 900 collaborators. Although most of Italy has been at least moderately well covered by

this effort, 7% of the 10 × 10 km units (chiefly in Basilicata and Sardegna [Sardinia]) have no records for any species.

A short chapter on altitudinal distribution presents data in the form of bar graphs by province and shows the results of a simple cluster analysis. Figure 4.1 (p. 142) would have been easier to use had the areas mentioned been clearly indicated on the map.

The final prelude to the accounts themselves is a checklist with taxonomic remarks. Ninety-one species (40 amphibians and 51 reptiles) inhabit Italian territory. The list is accompanied by extensive endnotes that provide useful information on dates of publication of names, ICZN rulings, recent generic allocations, and instances of taxonomic confusion, conflict, or uncertainty in the Italian herpetofauna.

The species accounts themselves begin with a convenient "how to read distributional maps" section. Each account except two of the sea turtles, *Chelonia mydas* and *Dermochelys coriacea*, and the naturalized Red-Eared slider, *Trachymys scripta*, is accompanied by full page, color, topographic map, marked with a half degree grid. Plotted points are divided into 1984 and earlier records, 1985 and later records from the SHI database, other records without specific locality (some provinces provided only imprecise localities to protect the animals), and doubtful records. Account sections are: taxonomy (including phylogenetics), general distribution, comments on the distribution map (often very detailed), habitat, altitudinal distribution, annual activity cycle, reproduction, and status of populations in Italy. All accounts are illustrated by multiple color photos. For some species these include eggs, larvae or juveniles, and views of courtship. In general the quality of the photos is good—only a photo of the venter of *Bombina pachypus* (p. 274) appears out of focus. The provenance of most photos is noted and the majority of photos actually depict Italian specimens.

Chapter 7 by Corti, Lo Cascio, and Razzetti is an overview of the Italian island herpetofaunas. The island groups include the relatively extensive island groups surrounding Sardinia and Sicily and off the coast of Tuscany, as well as the smaller archipelagoes and islands of Liguria, Latium (the Pontine Islands), Venetia, and southern Italy (Campania, Basilicata, Calabria, and Apulia). An extensive table provides species lists by island and a short text section outlines relevant literature and taxonomic issues. The islands have a disproportionately high number of outstanding taxonomic problems and conservation issues as many subspecies and even species have been described from them.

Razzetti and Sindaco briefly discuss 15 additional unconfirmed taxa that may or may not occur in Italy. Some are introductions (e.g., *Xenopus laevis* and *Agama agama*), whereas others approach the borders of Italy and might eventually be added to the fauna (e.g., *Rana arvalis* and *Pseudopus apodus*). Most interesting is the bizarre case of *Rana osca*, which the authors conclude is a synonym of *R. italica*—it was described multiple times, once in an unlocatable reference of uncertain date, and its type material appears to have disappeared within a decade of its description.

A biogeographic chapter by Bologna and Mazzotti reviews the geological history of Italy from the mid-Tertiary onwards and emphasizes the diversity of spatial patterns reflected by the herpetofauna and the resulting biogeographic mosaic. Among the faunal components recognized are widespread Euro-Asiatic elements, Western and Eastern Mediterranean forms, North African species, and peninsular, Sardinian, and Sicilian endemics. Of particular note are taxa with affinities outside of Europe, e.g., *Speleomantes* and *Proteus*, each with North American sister taxa. A variety of historical factors, including the Messinian salinity crisis and glacial advance and retreat, are proposed to explain some of the observed affinities of the fauna. Italian endemism at the species level is especially high for amphibians (50%), whereas reptile endemism is lower (17%) and largely restricted to Sardinia and Sicily, which are the most distinctive herpetofaunal regions of the country based on cluster analysis.

The last two chapters deal with herpetofaunal conservation and legislation. In Chapter 10, Roberto Sindaco evaluates the status of the Italian herpetofauna. Like most amphibians and reptiles worldwide, a lack of data regarding threats and population sizes necessitates categorization based chiefly on areas of occupancy and habitat fragmentation. All taxa are assigned to categories based on this information as well as the proportion of the global range in Italy and, for endemics, the specific nature of their distribution (e.g., insular or mainland). In the following chapter Vincenzo Ferri outlines the complex set of regulations than govern the protection of the herpetofauna. This includes European, Italian, and provincial statutes, some of which protect certain species and others of which focus on habitat protection. Tables summarize the categorization of each species under the Bern Convention, the European Union Habitats Directive, and CITES. All species are covered under the Bern Convention, and most by the Habitats Directive, but only sea turtles, tortoises, and *Vipera ursinii* are CITES listed. Twenty-one regional and provincial laws affecting amphibians and reptiles are also summarized.

As is fitting for such a comprehensive volume, the bibliography includes more than 1500 references, a resource in itself, as noted by Benedetto Lanza in his preface to the book. In a welcome change from many recent books, a good deal of care seems to have been paid to bibliographic accuracy. Finally the book concludes with short biographical sketches of the 54 authors who contributed to the volume, photo credits, and a taxonomic index listing entries by genus, species, and both English and Italian common name. Unfortunately, the references only relate to the species accounts proper; mentions in other chapters are not cited.

Aside from the inadequacy of the index, I find little to criticize in this aesthetically attractive volume. Although my knowledge of Italian is rudimentary, it appears that the English translation is faithful. The information provided is up-to-date and I especially appreciate the fact that potentially confusing taxonomic and distributional issues are explained and that the reader is lead to the original literature throughout the book. This volume is a testament to the vibrant herpetological community in Italy today. In addition to producing this atlas, the highly active Societas Herpetologica Italica has also recently launched the predominantly English language journal, *Acta Herpetologica*. I highly recommend the *Atlas of Italian Amphibians and Reptiles* to anyone with an interest in any aspect of the European herpetofauna.

No synthetic work on Homalopsidae has been published since the group's revision by the late Myanmar herpetologist Ko Ko Gyi, which dates back to 1970. Much research has been done since then, including many ecological and taxonomic studies by Daryl Karns, John C. Murphy, Harold K. Voris and their collaborators. Several species have been described or revalidated, others synonymized, and after nearly four decades the time is right for a new major work on these snakes. Taxonomically, the main recent contributor to the knowledge of this group is John C. Murphy, who (co-)described *Enhydris chanardi*, *E. gyii*, and *E. vorisi*. He is, thus, the best placed herpetologist to provide us with an overview of the group, and his new opus is a very welcome contribution.

The book includes two main parts, i.e., the introduction and keys (pp. 1–48) preceded by the preface and acknowledgments, and the generic and specific accounts (pp. 49–212) followed by the literature cited, appendices and the index to scientific names. The author recognizes 10 genera and 37 species in the Homalopsidae, and adds a section on three homalopsid-like *incertae sedis* snakes (*Anoplohydrus aemulans*, *Brachyorrhos albus*, and *B. jobiensis*), which might eventually turn out to be homalopsids once detailed taxonomic studies have been conducted.

The introduction provides a well-written presentation of the group, its general ecology and classification. Figure 1 shows a snake phylogeny to help understand the homalopsids' position among other snakes; its caption mentions that groups containing at least one aquatic representative are marked with an "A." However, no A was associated to *Grayia ornata*, a strictly aquatic snake, nor to the Boidae, which however contain freshwater snakes such as *Eunectes murinus* (see Pauwels et al., 2008 for a review of freshwater snake diversity). The introduction also includes a chapter co-authored by Brooks et al. on the water snake harvest at Tonlé Sap Lake, giving really impressive figures on the homalopsid meat and skin business in Cambodia.

The identification keys include all homalopsid snakes, but unfortunately not the three *incertae sedis* ones. These keys are not fully reliable, since many ranges of characters provided are in contradiction with those given in the species accounts. As an example, couplet 9a mentions that female *Enhydris jagorii* have more than 50 subcaudals, while the species account (p. 134) says they have 48–54 subcaudals, and that males have about 68, while the species account gives a variation of 53–68. Another example is that couplet 2a, "Nasal scales in contact" leads a.o. to *Myron richardsonii* (couplet 4c), which actually has separated nasal scales, as rightly mentioned in its species account. I noted in total 34 such discrepancies between the keys and the main text, with more-or-less significant consequences on species identification. It is also to be noted that there is no entry to couplet 9 of the key, excluding identification of snake specimens identifiable as *Enhydris jagorii* and *E. longicauda*. Consequently, an identification using these keys must be carefully double-checked with a comparison of the specimen to the presumably associated species account.

The generic and species accounts are well constructed, with clear sections on etymology, species content, distribution, and diagnosis, and a partial chreso-synonymy. Each species account includes a partial chreso-synonymy and sections on etymology, common names, distribution, diagnosis (except *Enhydris punctata*), size, external morphology, habitat, diet and feeding behavior, reproduction, relationships, and on the museum material examined by the author. In cases in which certain aspects of natural history are particularly well known, additonal sections have been added (predators, etc.). The chreso-synonymies are most often incomplete; their literature references are mentioned using the authors, dates, and abbreviated titles. Since there is a literature section at the end of the book, citing the authors and dates only in the chreso-synonymy would have been sufficient and would have saved a lot of space. The external morphology section follows the same organization for all species and this is helpful for interspecific comparisons. A point locality map is provided for each species. Unfortunately, although there was an effort to track literature references even in local journals, as stressed by Luiselli (2008) in his review of this book, many such references were not listed by the author and numerous localities are thus missing from the maps of many species, sometimes giving a misleading impression of rarity or disparate populations.

Most species are illustrated in life and in color—the book includes 76 color photos. One species only, *Brachyorrhos jobiensis*, is not illustrated at all. There are also 38 black-and-white plates, each composed of six pictures, showing details of head or body. Additional illustrations, mainly drawings, are provided in 47 figures throughout the book, and there are often several drawings per figure. The book is thus lavishly illustrated, most illustrations being of very good quality. A number of specimen photographs present important information, such as the only known picture of a live *Enhydris dussumieri*, or a very unusually patterned *Homalopsis buccata* from Songkhla Lake, southern Thailand. Many photographs are accompanied by precise locality data, which increases their informational value. The natural history of Homalopsidae is extremely interesting, and is well detailed for each species: specialized diets and habitats, hunting strategies, etc. Typical biotope photographs are provided for a number of species.

The main text often refers to the work of Gyi (1970), re-evaluating the accuracy of his observations and updating the data and diagnostic characters for each species, indicating real progress in

the knowledge of the group. The author moreover stresses a number of gaps in the current knowledge of homalopsids and highlights interesting variation among populations (see for example p. 75 for *Cerberus rynchops*), and thus provides useful directions for future research. The inclusion of species accounts for the *incertae sedis* species is also an excellent feature and underscores the need of additional taxonomic studies on these taxa.

The literature cited section (pp. 213–229) is not exhaustive, but provides all of the most important references. The most recent reference dates from 2007 (only one for that year). A number of references cited in the main text are not in the literature section, some perhaps due to a *lapsus calami* with respect to publication date. Among those referred to in the text and which were certainly omitted from the literature section (since the authors do not even appear in the literature section) are the following: Biswas and Acharyo (1977) (p. 121), Duvernoy (1832) (p. 24), Frith and Boswell (1978) (p. 63), Hundley (1964) (p. 95), Iskandar and Nio (1996) (p. 116, etc.), Kaup (1858) (p. 56), Mattison (1995) (p. 63), Mocquard (1907) (p. 139, 166, etc.), Obst (1977) (p. 155), Phisalix (1922) (p. 139), Reitinger (1978) (p. 148, etc.), Seba (1735, etc.) (p. 233), Shaw (1802) (p. 72, etc.), Sing et al. (1970) (p. 76, etc.) and Thu (2001) (p. 94, etc.). I will not list here the presumed associated references, since this would be too speculative given the possibility of erroneous dates.

Appendix 1 gives a list of species names and their current status, information on the type material and type locality. Appendix 2 is a summary of species distribution by country. This latter information must be used with caution, since I detected not less than 19 discrepancies between this table and the maps and/or text provided in the species accounts. Appendix 3 gives the maximal known sizes for each species. One regrets that the errata on p. 244 could not have been included within the main text.

The most disturbing weakness of the book is the huge number of misspellings. Indeed, I counted more than 450 misspelled words, and this figure is certainly not exhaustive. Most such mistakes are found in the scientific names, authors' names, and in the French and English citations (chreso-synonymy and literature cited). As an example, the binomen *Homalopsis buccata* was spelled five different ways. So many easy-to-detect mistakes and the existence of an errata section seems to indicate that the book was published in a hurry. It would have greatly benefitted from a careful reading, particularly by French- and German-speaking herpetologists, since so many important literature references were written in these languages.

Discrepancies between character variations are not limited to the above mentioned contradictions between the keys and the species accounts. These discrepancies are also found within the text and between the text and tables. A striking example is found in the *Enhydris jagorii* species account (p. 133), where the type specimen is described twice, once in the left column, once in the right one. For the same specimen and on the same page, two different total lengths are given (463 vs. 471 mm), as well as two dorsal scale row numbers before vent (21 vs. 20) and two numbers of subcaudal scales (86 vs. 68). Another example is found in the *Enhydris punctata* species account, where one reads "The subcaudal scales are divided and number 27–46 (32–44 in females, 46–48 in males)." The diagnosis for *Myron richardsonii* (p. 205) mentions that the species has a white belly, while a picture on the same page shows a yellowish-pinkish belly with transverse lines on each ventral and a black mid-line; and so on. Often these discrepancies have an influence on the diagnosis and species identification. For instance, on p. 168 *Enhydris subtaeniata* is compared with *E. enhydris*. Their respective ventral scale numbers are given as 136–153 vs. 153–174, thus with nearly no overlap. However, on p. 170, the minimum ventral scale number for *E. subtaeniata* is given as 134, and on p. 118 (Table 9) the minimum number for *E. enhydris* is given as 148; their ventral numbers are thus to be corrected to 134–153 and 148–174, respectively, this time with a wide overlap. In addition to the discrepancies in morphological variation between the keys and the main text, I noted 106 problems within and between the main text and the tables, or sometimes between the text and the figures; this number does not include the discrepancies between the main text and Appendix 2. Tables 5, 6, and 11 exhibit an especially large number of discrepancies with the associated species accounts and information available on figures.

The preface explains that the main goal of the book is threefold: to "provide a means of identification for the species of homalopsid snakes, clear up some taxonomic confusion, and provide the reader with a summary of what is known about their natural history." With the caveat indicated above, i.e., always carefully compare a key-based identification with the associated species account, the book indeed does provide a means for identification. The second and third goals are achieved more successfully, and this makes of the present book an important reference to have not only for all herpetologists, but also for readers interested in general natural history and Southeast Asia. The price indicated on Krieger Publishing's website for the book is US $68.50. Given the very good binding and glossy paper quality, the well-illustrated hard cover, the high number of color pictures and the important content of the book, this is a very reasonable price. I thank Patrick David (Muséum National d'Histoire Naturelle, Paris) for useful comments on this review.

This book is the English translation of the third edition of the original French language work. It is difficult to know what the three authors set out to accomplish with this book, as there is neither a foreword nor a preface. Peter Pritchard, however, in his "translator's notes," suggests that their intent is to distinguish the book from other works with a chelonian world view by being taxonomically up-to-date and by including discussions of survival status.

This book is divided into two major sections, General Biology (9 pp.), and Identification (401 pp.), followed by a short list of references and index of scientific names. The volume is illustrated by 403 photos, two diagrams, and numerous maps. The binding and paper are of high quality, and there are handy colored page margins organized by family or section description throughout.

General Biology begins with a description of the placement of chelonians among living things. *Proganochelys*, considered by the authors the ancestor [sic] of all turtles, is the basis for further taxonomic discussion. The unique chelonian skeleton and other organ systems are treated in about one page, as are senses, sexual dimorphism, metabolism, ethology, and threats and protection. Caveats about taxonomy being a dynamic science always find their way into turtle books; there is a single highlighted paragraph at the end of the General Biology section which states that the nomenclatural concepts in the book incorporate many recent changes by Roger Bour, and that only minor disagreements are to be expected from turtle systematists around the world.

The Identification section is organized alphabetically by family, genus and species, first within Pleurodira, then within Cryptodira. There are 311 species accounts, 280 of which have at least one accompanying photo (of those lacking photos, over half have been described since 1950). Each species account begins with the scientific name, author, and year of description. Common names are also provided, but appear in the page margin adjacent to the reference maps (see below). Most accounts are divided into the subsections Distribution, Description, Natural History, and Protection, each of which may be followed by just one sentence or several detailed paragraphs for the chelonian of interest. A few accounts also include extra sections, such as 'Ethnozoology' for *Carettochelys insculpta* and *Centrochelys* (*Geochelone*) *sulcata*. Some short sections of text were inadvertently left untranslated and appear in the original French, as in the introduction to the Platysternidae (p. 116).

All accounts have a shaded range map indicating the approximate distribution of each species. In the page margin of each account is a continental scale reference map with a square box indicating the location of the more detailed distribution map featured in the main part of the account. Several of the range descriptions from the text are not in agreement with the distribution maps. Associated specimen photos are placed at various places within their respective accounts, but most figure legends do not mention the species name. As a consequence, the identity of photos immediately following the text for one species and preceding that for the next may be unclear to readers. Most of the photos are acceptable, but several have severe shadows, show animals posed in people's hands, or have poor depth-of-field. Interestingly, there is a short biographical appreciation of John Cann on page 30, lauding his skills as a photographer. Indeed, Cann's photos are as near perfect as they can be—no shadows, excellent focus, and alert subjects looking at the camera, always in a natural setting and pose. It is unfortunate that only six of his photos were included in the book!

The Distribution subsection uses both geographic features (rivers or mountains) and political boundaries for a general idea of the range. While usually straight forward, there are some confusing mix ups in this section, e.g., in the range description for *Manouria impressa*, it seems there was an intended comparison with *M. emys*, but the text reads as if to compare *M. impressa* with itself. 'Description' includes a general color and size scheme for the species as well as any other noteworthy shell, skin, or coloration feature. The Natural History subsection lists habitat type within the occupied range; some diet and reproductive information may be included too. The Protection text includes an incomplete listing of national and international laws or treaties that offer some level of legal protection. Appendix III listings under CITES are not included, and some species covered under Appendices I or II are not listed as such. Status, as listed by the IUCN and/ot the Turtle Conservation Fund, is sporadically noted and localized threats or conservation practices known to the authors are also mentioned. Protective status is always in flux, but the simple consistent reference to CITES, IUCN, and Turtle Conservation Fund status for each species would have increased the utility of the book.

Most references included in species accounts cannot be found in the book's reference section. For example, the account for the Pantanal swamp turtle, *Acanthochelys macrocephala*, cites "Buskirk (1988)" for documentation of Paraguay within the range of the species. Neither this paper, published in *Herpetological Review*, or any other senior authored works by Buskirk appear in the reference list. This systematic oversight severely hampers the use of the book by anyone wishing to obtain further information. Additionally there are errors for the works that are listed. *Turtle and Tortoise Newsletter* (TTN) is listed under "Kalb, J.H. 1992." Heather Kalb was one of two editors for the premier issue of this newsletter that was first published in January 2000, with a publication city and state of Lunenburg, Massachusetts, not Evansville, Indiana as the citation reads. The parent publication for TTN, is the peer reviewed journal *Chelonian Conservation and Biology*

which is listed under "Rhodin, A.," who is a founding editor, and sometime author in this journal, which was first published in November 1993, not 1997 as the citation reads.

The index of scientific names only lists taxa by genus, then species, following the authors' taxonomic interpretation. This does not provide user-friendly access, particularly in light of the taxonomic and nomenclatural changes that have occurred in recent years. For instance, the Western Pond turtle of North America cannot be found under the still widely used name *Clemmys marmorata*, but only under *Actinemys marmorata*. At a minimum, cross-listing by specific epithet followed by genus would have greatly facilitated reader use of the index.

After only two years, the English edition of *Turtles of the World* is already in its second printing. The online library catalogue WorldCat (www.worldcat.org) shows that at least 448 institutional libraries worldwide have a copy. It would be prudent for the thrifty turtle book enthusiast to seek one of these library holdings to inspect a copy before making a purchase.

e-mail: aaron.bauer@villanova.edu

Jean Raffaëlli has produced a strange, but useful and inspiring book on salamanders. *Les Urodèles du Monde* can best be understood in light of author's own background, interests, and motivations, which are summarized in the 26 pages of "L'aventure personnelle autour des salamanders." Raffaëlli began his personal odyssey with salamanders in his native France, studying them both in the field and in the terrarium. His love of all things urodelan led him to expand, not only his captive studies, but his field work to encompass much of the world, but particularly the Americas, where salamander diversity is greatest. Raffaëlli's narrative incorporates comments on and by a diversity of salamander experts from both Europe (e.g., Marc Alcher, Robert Thorn) and America (e.g., David Wake, James Hanken, Richard Highton, C. Kenneth Dodd, Jr.), all of whom have influenced his passion for salamanders or contributed to his own knowledge of and appreciation for these amphibians. This personal background, which also touches on chytrid fungus, habitat destruction in Mexico, and the secrets of maintaining salamanders in captivity, is illustrated by small photos of the people, places and salamanders that have made the deepest impressions on him.

The main body of the book consists of concise species accounts of all salamander taxa recognized as of June 2006. These have drawn heavily from the Global Amphibian Assessment (GAA; www.globalamphibians.org), using GAA threat categories, maps, and estimates of extent of occurrence. For each taxon (subspecies through all higher order ranks within Amphibia) the author and date of description are provided and for all groupings less inclusive than Urodela there is accompanying text. For supraspecific categories, diagnostic features, fossils, phylogeny and taxonomy are discussed. The currency of the taxonomy is impressive. I suspect that many of the genera, subgenera, and species detailed will be unfamiliar, even to most amphibian specialists, unless their own knowledge of the literature is both global and comprehensive.

Each species/subspecies account (all recognized forms, as well as several undescribed forms of *Chiropterotriton* and *Pachytriton*, are illustrated and discussed) occupies between a quarter of a half-page column and a full page. Although not divided into discrete subsections, each account provides information about taxonomy (particularly recent changes), characteristic features, color (including ontogenetic and sexual variation), habitat, reproduction (number of eggs, phenology), diet, threats, distribution (including extent of occurrence), and GAA threat/status category. For some accounts a separate "note d'élevage," in bold, provides husbandry observations. More extensive husbandry information is provided in boxed features scattered throughout the text and tailored for groups with similar housing and rearing requirements (e.g., ambystomatids, *Triturus* and related genera plus *Cynops*, *Plethodon*, small-bodied bolitoglossines).

The main complaint that I had and, I suspect, most readers will have is with the maps and illustrations. Each species account has a small (and I mean small!, mostly ~35 × 33 mm) map associated with it (subspecies are typically shown together on a single map, which for *Salamandra salamandra*, with 15 subspecies, is a problem). These are sometimes sufficient to allow the reader to get his/her bearings, but in other cases all but the most geographically savvy will be lost. In many instances the range markings on the maps are so small and inconspicuous that only careful inspection reveals them (a surprisingly large number of species have areas of occurrence of <20 km^2). This is particularly problematic for high elevation forms, as the red distribution shading is hard to distinguish from the reddish-orange used to denote areas of high elevation on the maps (see for example *Tylototriton verrucosus*, p. 145, as well as many of the bolitoglossine maps). In some cases the maps extend to the absolute inner margins of the page, nearly disappearing in the binding.

The illustrations are also almost uniformly too small. The vertebrate phylogeny on p. 35, for example, is nearly unreadable. Even the larger photos are only 60 × 40 mm, whereas some of the smallest are 30 × 20 mm. In part, this is the result of using (with permission) downloaded low resolution images from AmphibiaWeb. Adults of most taxa are illustrated by color photo-

graphs (although there are none for any of the five species of the subgenus *Oaxakia* within *Bolitoglossa* and few of *Oedipina*), and in some instances larvae and/or eggs are also depicted. For some Chinese taxa colored drawings are provided instead and in some cases, chiefly within the *Ambystoma tigrinum* group, museum specimens have been photographed. The photos come from many sources and, as such, are highly variable in quality. Some are adequate to illustrate diagnostic features, but many, especially given their small size, leave much to be desired. In one case the same photo, showing *Ambystoma macrodactylum* eggs, has been used twice (pp. 76 and 97). Some photos are on neutral backgrounds, others are clearly taken in aquaria or terraria, and still others on naturalistic backgrounds. On page 113 a photo of *Ommatotriton vittatus cilicensis* floating in a water column has an out of focus street scene behind it!

The text concludes with a table comparing the suprageneric taxonomy of Dubois (2005) with that of Frost et al. (2006) and a large table summarizing the familial and less inclusive taxonomy employed in the book, with allocation to subgenera, species groups and complexes as well as genera noted. There is a glossary of 58 terms and a bibliography of >450 references. The index entries are by genus only, except (rather confusingly) for species group names, such as "*dunni*" and "*elongatus*," which appear without reference to the genera to which they belong. At least one taxon, *Pseudoeurycea cephalica rubrimembris*, is not indexed, despite having a full text account.

What makes this book so unique is the juxtaposition of information of various types. On the one hand, the book should appeal to herpetoculturalists who specialize in urodeles. In comparison to other groups of amphibians and reptiles, the literature on salamander husbandry is limited, and Rafaëlli has provided concise, taxon-specific information about the care and breeding of most groups. On the other hand, the book's species accounts provide the only complete summarization of all living salamanders using current taxonomy in book form, and should be attractive to systematists and conservationists. Although much of the information is available from the Global Amphibian Assessment, Raffaëlli has added material and, of course, made everything available in book form. These two seemingly disparate elements of the book, however, make perfect sense in light of the third component — the author's autobiographical introduction. I especially enjoyed reading this "personal adventure" and suspect that it might inspire some readers with rather focused interests to expand their horizons and appreciate the "holistic salamander" as it is clear the author does. Jean Raffaëlli has written a book not for herpetoculturalists or for systematists, but for those, like himself, with an abiding fondness for urodeles in all contexts. On a more practical note, despite the too small images, *Les Urodèles du Monde* has become my "go to" source for basic information about salamanders on a global scale. For anyone with a serious interest in salamanders, amateur or professional, this book will serve as a global urodelan who's who.

e-mail: aaron.bauer@villanova.edu

This book is a new edition of a work initially published in 1980 and subsequently revised and released as a CD-ROM (McCoy 2000). The geographic scope of the volume includes the entirety of the nation of Solomon Islands, including the Santa Cruz Group to the southeast of the main Solomon chain, and Bougainville and nearby islands, which constitute a part of the North Solomons and are politically part of Papua New Guinea. The reptile fauna of the Solomons is both species-rich (86 species), and phylogenetically diverse. Lying close to New Guinea, these islands support reptiles, such as crocodiles, varanids, agamids, acrochordids, and terrestrial elapids, that are lacking from most of the more distant island groups of Oceania. Among the more widely-distributed scincid lizards, the Solomons boasts 11 genera, including the monotypic endemics *Corucia zebrata*, which was CITES listed in 2002, and *Geomyersia glabra*, and 16 species of *Emoia*. The need for a new edition of this work is clear given both the taxonomic advances and environmental losses (particularly the degradation of lowland forests and impact of the pet trade) of the last quarter century.

The introduction includes a brief overview of the topography, geological history, and climate of the region, and an explanation of the species accounts, each of which includes information on English and Latin names, author and date of description, distribution (extralimital and within the Solomons) and type locality, description (based on specimens and published data), color and pattern (based chiefly on observations of live specimens), and natural history. In general, the most recent taxonomic revisions have been followed, for example Zug (2004) for *Carlia*, and Manthey and Denzer (2006) for *Hypsilurus*. McCoy also provides insight (usually based on consultation with experts on particular groups) into remaining taxonomic problems, indicating that *Lepidodactylus guppyi*, *Emoia pseudocyanura*, and *Sphenomorphuis solomonis* are probably composite, signaling the presence of an undescribed species of *Sphenomorphus* (listed as *S. undulatus* by McCoy 1980),

noting that *Sphenomorphus bignelli* is currently incorrectly assigned to genus, and rejecting the validity of *Varanus juxtindicus* (Böhme et al. 2002) from Rennell Island. His observation that Solomons populations of *Cyrtodactylus louisiadensis* are probably not conspecific with those from the Louisiade Archipelago has subsequently been confirmed and *C. solomonensis* has been erected to accommodate these geckos (Rösler et al. 2007).

Keys are provided for marine turtles and for families and genera of lizards and snakes. Keys to species are also presented for all genera with two or more species. One significant problem is that the keys for geckos, as well as the corresponding text in species accounts, confuse digit I and digit V (e.g., on pp. 28 and 36 *Hemiphyllodactylus* is said to have a reduced and clawless digit V, whereas these features characterize digit I only). This error has some potential ramifications; most importantly, are the reported lamellar counts for digit IV (a standard character reported for geckos with scansors) actually referring to digit II because of the incorrect polarity? This aside, I noted only two substantive errors in the text: 1) Sprackland is credited as author of *Varanus spinulosus*, but the taxon was actually described by Mertens (1941) and subsequently elevated to full species by Sprackland (1994); and 2) *Ramphotyphlops angusticeps* is listed as occurring in New Caledonia as well as the Solomons; the New Caledonian type locality, and sole record, is considered incorrect (Bauer and Sadlier 2000).

Some of the most useful and interesting aspects of the text relate to the natural history notes, many of which are drawn from McCoy's own observations. While a few accounts, most notably that of *Corucia zebrata*, cite other sources, the majority of natural history data are unreferenced. At least for serious users of the book, it would have been beneficial to have citations in the relevant primary literature (e.g., pseudocopulation in *Lepidodactylus lugubris*, p. 41).

This new edition is far better illustrated than McCoy's first edition. Most taxa are illustrated by color photos (exceptions include *Caretta caretta*, *Dermochelys coriacea*, *Hypsilurus longii*, *Lepidodactylus mutahi*, *L. shebae*, *Acutotyphlops kunuaensis*, *A. solomonis*, *Ramphotyphlops mansuetus*, and the three regional *Hydrophis*) that appear two per page—large enough to be useful. Not only are the photos generally sharp and illustrative of important features, they are also accompanied by localities, with all but four species represented by animals from the Solomons. A few rare species are represented by photos of preserved specimens (*Sphenomorphus fragosus*, *S. tanneri*, *S. taylori*, *S. transversus*, *Parapistocalamus hedigeri*), but these are also of high quality. In comparison with the first edition (McCoy 1980), which had 20 plates (8, with 64 separate photos, in color), the current version has 128 color photos. The current volume is also nearly twice the length of the older book and offers a new set of checklists giving the occurrence of reptiles for each of 17 islands or island groups within the Solomons. The 82-entry glossary is essentially unchanged from the 1980 edition and the literature cited includes 71 references, only 15 more than the older book, but with many older entries replaced by more recent ones. A few seemingly relevant citations are missing but given that the corresponding text is not intended to be a technical monographic this is understandable. Only the index is a disappointment by comparison with the earlier book; the 1980 index conveniently included index entries by specific epithet as well as genus, whereas the 2006 index lists entries only by genus.

Although not every herpetologist needs a guide to the reptiles of the Solomon Islands, those who do will find this book to be concise, authoritative, and well illustrated. Although Euro prices make the book relatively expensive by American standards, it is the only up-to-date source for the region and should certainly find a place on the shelves of anyone working on insular herpetofaunas or interested in Pacific biodiversity.

Erratum

In the article "Detection of Crotamine and Crotoxin Gene Sequences in Genomic DNA from Formaldehyde-fixed Rattlesnakes" by Corrêa et al., published in Volume 38, Number 2 (2007) of *Herpetological Review*, PCR conditions indicated on p. 159 should have read: 0.2 mM of dNTP, 2 mM of MgCl2 and 0.6 U of Taq polymerase.

A New Batrachological Reprint

Jean-Louis AMIET

Publications sur les Batraciens du Cameroun

From 1970 to 2007, Jean-Louis AMIET published 53 papers dealing with the amphibians of Cameroun. These papers covered many fields of the study of these animals: systematics (description of 42 new taxa), ethology, ecology, faunistics. Most of these papers were published in periodicals which no longer exist and may be difficult to find, especially for young biologists who do not have direct access to major libraries. The author decided to prepare a complete facsimile reprint of these works, including in many cases post-scriptum notes providing additional unpublished information on the topic of the paper.

The whole reprint covers 1587 pages, published by ISSCA as two separate volumes that will constitute the first two issues of *Monalytes*, a new series of batrachological monographs issued by ISSCA. Both volumes will be published in 2008. Volume 1 (748 pages) covers the period 1970–1980.

PRICES

INDIVIDUALS.—*Monalytes* (single volume **1 or 2**), 40 € or 60 $ (within Europe); 60 € or 97.50 $ (outside Europe). *Monalytes* (both volumes **1** and **2**), 70 € or 105 $ (within Europe); 110 € or 180 $ (outside Europe).

INSTITUTIONS.—*Monalytes* (single volume **1 or 2**), 80 € or 120 $ (within Europe);100 € or 157.50 $ (outside Europe). *Monalytes* (both volumes **1** and **2**), 140 € or 210 $ (within Europe); 180 € or 285 $ (outside Europe).

Prices shown include surface mailing, non-registered. For other conditions of mailing, contact our secretariat.

MODES OF PAYMENT

- In Euros, by cheque **drawn on a French bank** payable to "ISSCA," sent to: ISSCA, Reptiles & Amphibiens, Departement de Systematique & Evolution, Museum National d'Histoire Naturelle, CP 30, 25 rue Cuvier, 75005 Paris, France.
- In Euros, by direct postal transfer to our postal account: "ISSCA," Nr. 1-398-91 L, Paris. **If you use this mode of payment, add 2.50 € to your payment for postal charges at our end.**
- In US Dollars, by credit card or by cheque sent to: Bibliomania!, P.O. Box 58355, Salt Lake City, UT 84158, USA; phone/fax: +1-801-562-2660; e-mail: Breck@Herplit.com.

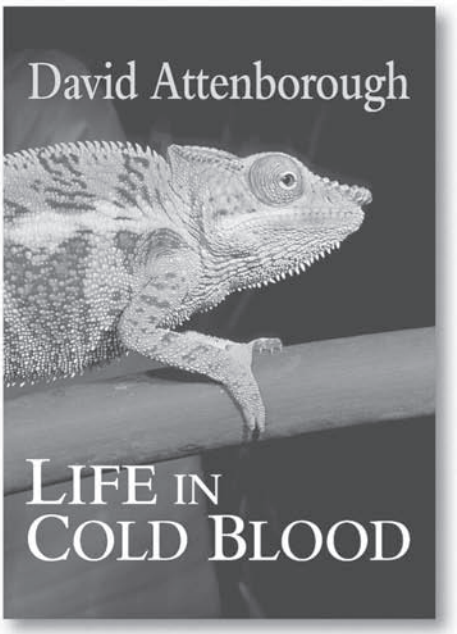
NOMBRES ESTÁNDAR EN ESPAÑOL EN INGLÉS Y NOMBRES CIENTÍFICOS DE LOS ANFIBIOS Y REPTILES DE MÉXICO
STANDARD SPANISH, ENGLISH AND SCIENTIFIC NAMES OF THE AMPHIBIANS AND REPTILES OF MEXICO
Second Edition

Edited by ERNEST A. LINER and GUSTAVO CASAS-ANDREU

This fully bilingual list covers 1624 taxa and incorporates all taxonomic changes since the 1994 edition. This is a must for anyone working with Mexican herpetology. Formatted to be a companion to Crother (ed.) 2008. 163 pages.
July 2008. ISBN 978-0-916984-75-3



Prices: Prepublication (SSAR members only)		After November 30, 2008	US $16.00
first copy -	US $12.00	USA Shipping : First copy	US $3.00
additional copies	US $10.00	Additional copies	US $2.00

Special Offer - Purchase

Crother 2008 - Herp Circ 37 - US & Canada Names List and *Liner and Cavas-Andreu - Herp Circ 38* for US $20.00, plus shipping, during the pre-pub period.

Send orders to: Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158-0517, USA. Telephone / fax 801-562-2660; email: ssar@herplit.com. Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MasterCard (Account number and expiration date must be provided). SSAR membership details and a complete list of Society publications can be obtained on request from the Publications Secretary.

The Illustrated Companion to the Television Show

Life in Cold Blood

David Attenborough

Life in Cold Blood offers a rare glimpse into the peculiar world of amphibians and reptiles, the first vertebrate creatures to venture forth from the primeval waters millions of years ago, yet which today include species that are the most at risk of extinction. Join acclaimed naturalist Sir David Attenborough as he travels to the far corners of the Earth to tell the epic story of these animals. Discover the secrets of their astounding success—and the profound implications of their uncertain future.

"Admirably illustrated, this book completes David Attenborough's great exploration of the world's main animal groups. He shows us the lives of amphibians and reptiles in all the fascinating detail we have come to expect from him. A treasure trove for everyone—from the child seeing flying dragons or man-eating crocodiles for the first time to the professional zoologist realizing that there is still much to learn."
—Philip Rainbow, Natural History Museum, London

288 pages. 200 color illus. 7 x 10.

Cloth $29.95 978-0-691-13718-6

Amphibians & Reptiles
of the State of
Chihuahua, Mexico
Julio A. Lemos Espinal & Hobart M. Smith

The most comprehensive text on the amphibians and reptiles of the state of Chihuahua, Mexico. Contains taxonomic keys, in depth species descriptions, color photographs, gazetteer, dot distribution maps, and localities of collection. Complete text in both Spanish and English

Specifications: xii, 613 pages, 8½ x 11 inches. Paperback (ISBN: 970-9000-41-1) $90.00 + postage.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution or Natural History notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order form will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Allen Press, Inc., P.O. Box 1897, Lawrence, KS 66044, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Regarding missing or damaged issues, please notify *Herpetological Review*, Allen Press, Inc., P.O. Box 1897, Lawrence, KS 66044, USA (tel. 785/843-1234 or e-mail: herps@allenpress.com).

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 840		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

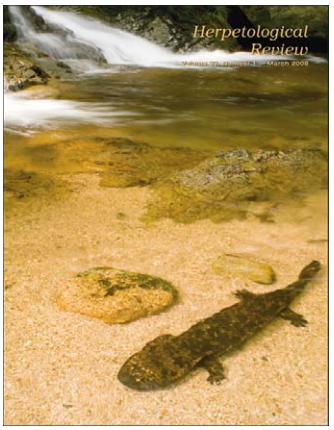
www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2008 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its newsjournal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.



To join SSAR or to renew your membership, please visit the secure online Allen Press website:

http://timssnet.allenpress.com/ECOMSSAR/timssnet/common/tnt_frontpage.cfm

Future Annual Meetings

2008 — Montreal, Canada, 23–28 July (with ASIH, HL)
2009 — Portland, Oregon, 22–27 July (with ASIH, HL)
2010 — Providence, Rhode Island, 7–12 July (with ASIH, HL)
2011 — Minneapolis, Minnesota, 6–11 July (with ASIH, HL)

About Our Cover: *Andrias japonicus*

Clear, cold mountain streams drain the rugged mountains of Japan's Honshu, Shikoku, and Kyushu islands. At one site on Honshu Island, at an elevation > 500 m, the riverbed is rocky and water-swept. Oak and maple trees grow in the surrounding closed canopy forest along with clusters of bamboo. Cold temperatures and constant agitation of the water produce a highly oxygenated environment. Lurking beneath the waters of these clear mountain streams is the Japanese Giant Salamander, *Andrias japonicus*. *Andrias* contains two living species: *japonicus* and *davidianus* (from China). Together with the North American Hellbender (*Cryptobranchus alleganiensis*), these are the only living members of the ancient family Cryptobranchidae. This group is remarkable both for containing the largest living amphibians (the two species of *Andrias*, to ~ 1.5 m TL) and displaying a remarkable geography—two species in eastern Asia and one in eastern North America.

The breeding season for *A. japonicus* spans August to September when males compete to control breeding sites. The breeding sites consist of grottos and cubbies in the waterway that are protected enough for the male to guard eggs deposited there. Male competition for these sites can be fierce, even resulting in death. Males that retain control of the sites are referred to as "den masters." Females deposit clutches of 400–500 eggs within the dens, which the males guard until the larvae hatch and disperse. The larvae take 4 or 5 years to metamorphose into an adult form. Captive animals have lived > 50 yrs. Wild longevities are still not clearly understood.

Danté Fenolio was in Japan (with funding from the Javitch Foundation) visiting research biologist Sumio Okada (Ph.D. student at Shimane University). Okada has been monitoring several populations of *Andrias* for over 7 years with pit tags in roughly 650 individuals. This work is critical in developing an understanding of the population ecology and habitat requirements of these ancient animals. Fenolio met an elderly gentleman in one such village who has interacted with *A. japonicus* since the pre-World War II era. His descriptions of the sizes of animals he has encountered and their abundance, past and present, speaks to a slow but steady decline of the species. The salamander on our cover resides in a stream that is slated for a controversial hydroelectric dam. Public awareness about the plight of these salamanders is increasing and a television special featuring Sumio and his work recently aired on the National Geographic Channel.

Fenolio's photograph of our cover subject came about with the assistance of Sumio Okada, who led Danté to the mountain stream locality on Honshu Island where they encountered the salamander. Wildlife photographer Michael Ready shared a tip involving a flash method to create the "foggy" look in the waterfall while keeping the salamander in the foreground crisp and well lit. The photo was taken with a Konica-Minolta 5D, Minolta 24mm lens on a tripod, with a Sony twin-flash unit.

Danté Fenolio is a Ph.D. Candidate at the University of Miami and a recent hire by the Atlanta Botanical Garden for their amphibian conservation program. His research focuses on subterranean biodiversity and amphibian ecology/systematics. Mike Ready took this image of him at the Tottori Prefectural Museum, Japan, and it is used here with their permission. The preserved *Andrias japonicus* shown here was 143 cm long (TL) with a mass of 44.3 kg at the time of death.

SSAR BUSINESS

New Opportunities for Students at Montréal Meeting

There was much discussion at the 2007 St. Louis Annual Meeting regarding student involvement in SSAR and how to make the Annual Meeting more accessible to students and encourage their attendance. With this in mind, a Student Participation Committee was formed (Dawn Wilson, Chair) and plans are underway to change a number of aspects of the meeting. The 2008 Joint Meeting of Ichthyologists and Herpetologists will be held in Montréal, Canada, July 23–28. SSAR is planning two new events specifically for our student members. We will hold a lunch meeting (pizza provided) with the members of the Student Participation Committee, several members of the Board, and those students who want to take a more active role in the Society. Every year we look for students to serve on committees and editorial boards, organize events at our Annual Meeting, etc. If you have an interest in serving the Society in any capacity, the Board needs to know who you are! Additionally we are planning an evening students-only social immediately prior to the opening general reception (finger food plus drink tickets provided). Board members and a number of senior herpetologists will be in attendance and there will be ample opportunities to meet and talk with younger members of the Society.

We wish to issue a reminder that the Board Meeting (which will be held on July 22) is open to all members of the Society and everyone is encouraged to attend. Because we know that most members are not usually able to arrive a day early, we will be changing the format of the Business Meeting (usually held on the 4th day of the meeting) so that it will now more closely resemble a Board Meeting. Officers and Editors will be in attendance and will each present a brief Annual Report and a summary of upcoming plans. Audience participation will be expected.

We hope that these changes will encourage all of our members, especially students, to continue to support our Society and attend our Annual Meeting. SSAR is proud of its student roots and rec-

ognizes that the future of our organization rests on continued student involvement.

The Student Participation Committee welcomes feedback or suggestions from any interested member (e-mail: dwilson@amnh.org). We hope to see many of you in Montréal.

—Marion Preest, SSAR Secretary

SSAR Henri Seibert Awards for 2008

The Henri Seibert Awards were initiated in 1992 to provide recognition for the best student papers presented at the annual meeting of the SSAR. To be eligible, the presented paper must be the result of research by the individual making the presentation. The research must have been conducted while the student was enrolled in either an undergraduate or graduate degree program. Please refer to *Herpetological Review* 28(4):175 and the SSAR website (http://www.ssarherps.org/pages/seibert.php) for recommendations to students entering the Henri Seibert Competition. Students entering the competition must be members of SSAR. The presentations will be judged by the SSAR student prize committee. One Henri Seibert Award of US $200 may be given in each of the following **four** categories: **Systematics/Evolution**, **Ecology**, **Physiology/Morphology**, and **Conservation**. Students may win the award only one time. Please indicate the appropriate category for which you are applying on the abstract submission form. Announcement of winners will be made at the **SSAR Business Meeting**. All participants should be present at the business meeting. Contact Patrick Owen for further information: owen.133@osu.edu.

6th World Congress of Herpetology Manaus, Amazonas, Brazil

We are preparing for a bumper crop of herpetologists from throughout the world to join us for the event of the millenia—the 6th World Congress of Herpetology, to be held jointly with SSAR, in Manaus, Amazonas, Brazil 17–22 August 2008. This will be first World Congress in the New World and it will be done with all of the flare and pomp of the First World Congress, with the added signature touch that people have appreciated in the SSAR-HL congresses I ran in Veracruz in 1987 and Manaus 2003. I will not try to outdo these, but come and see if I do! Remember my motto—no tickets, no lines, no limits!

Please see our website (www.worldcongressofherpetology.org). It is a dynamic site; as events and offers are solidifying they are being placed on the web, so visit us often.

It is our pleasure to host this meeting on the shores of the Rio Negro, in the heart of the Amazon Rainforest at the five-star Tropical Hotel. Since you are coming all this way, take some time before or after the meeting to go out and see the forest or take a river trip. Set up your own groups to go on river trips, many of the plenary speakers and symposium organizers will be accompanying post-meeting river trips, so you will have days to talk with some of the greats in herpetology on a one to one basis. Contact Vic Hutchison for his special Varig Airline Affiliated post meeting birding tours to the patanal.

Field trips along jungle rivers can be programmed aboard boats like our boat the *Enigma*, allowing total comfort and safety while fishing or observing wildlife.

On Sunday afternoon there will be a special session on "Amphibian Conservation: Moving from Global to Regional Planning" organized by Don Church of Conservation International, with an interval for the first plenary lecture, followed by a dinner and awards session for the invited members of the Amphibian Conservation session.

Each session of the meeting, from Monday–Friday, will begin with lectures by plenary speakers, followed by either symposia or contributed papers. Access to posters will be available all day, culminating with a happy hour session at the end of each afternoon when the poster authors will be available for discussions. There will be the traditional Monday night social icebreaker with regionally produced beverages, finger food, and regional dance show. Tuesday evening will be a special event—the Secretary General of the World Congress birthday party. Wednesday night will be a picnic (Churrasco) on the white sand beach of the Negro River complete with a Boi Boom Ba live dance show. Thursday night will be the traditional turtle group "lunch" as well as other optional choices such as trips to the Opera House, music and dance houses such as Remulos. Friday evening will be the final plenary presentation by Ian Swingland during the Banquet, followed by the AIHA sponsored live auction, and discotec until dawn.

Plenary Speakers

We have gathered a prestigious group of plenary speakers, known not only for the excellence of their science but also for their communication and entertainment skills. There will be no heads nodding in the aisles when these herpetologists are performing!

—William E. Magnusson, INPA. The evolution of herpetological studies in the Amazon. Sunday evening welcome address.
—Russell Mittermeier, President, Conservation International. Global priorities in reptile and amphibian Conservation. Keynote speaker.
—Darrel Frost, American Museum of Natural History, E.D. Cope Honorary Speaker. The past, present, and future of the science of amphibian systematics.
—Peter Narins, UCLA. Exploring frog communication behavior: continuing adventures of an expeditionary biologist.

—Michael Bull, Flinders University, Australia. Lizard social behavior and conservation: lessons from an Australian skink.
—Richard Shine, University of Sydney. Invasion biology and impact of cane toads in Australia—the way it really is!
—John M. Legler, Professor Emeritus, University of Utah. Turtles: a paradigm of versatility and venerability.
—Fred Allendorf, University of Montana. Genetic effects of habitat fragmentation.
—Jonathan Losos, Harvard University. Evolutionary diversification on islands and mainlands: historical contingency and adaptive radiation in *Anolis* lizards.
—Aaron Bauer, Villanova University. Spatial and temporal history of geckos of the world.
—Ian Swingland, Director of the First World Congress of Herpetology, from his world base in Kent. Peeling peaches in the pampas.
—James Parham, California Academy of Sciences. Human impact on the diversity, distribution, and systematics of turtles.
—Oscar Flores-Villela, UNAM. The making of a national herpetofauna, the herpetofauna of Mexico.
—Marvalee Wake, University of California, Berkeley. Evolution of amphibian viviparity and the origins of homoplasies.
—Celio Haddad, Universidade Estadual Paulista Júlio de Mesquita Filho (UNESP, Campus de Rio Claro). Reproductive behavior in anuran amphibians.

Featured Symposia

—Reproduction in Reptiles: From Genes to Ecology. Michael B. Thompson & Scott L. Parker, organizers.

—Invasive Reptiles and Amphibians: Global Perspectives and local solutions. Robert Reed, organizer.

—Sensory Ecology of Anuran Communication. T. Ulmar Grafe & Peter M. Narins, organizers.

—Evolutionary Transitions of Body Shape in Extant Amphibians and Reptiles: Call for Integrative Approaches. Tiana Kohlsdorf, organizer.

—Herpetofaunal Reintroductions, Translocations, and Supplementations. Jennifer M. Germano & Phillip J. Bishop, organizers.

—Disease and Amphibian Declines—Where Do We Go from Here? Jean-Marc Hero, Erin Muths, & Trenton W. J. Garner, organizers.

—The Biology and Management of Crocodilians. John Thorbjarnarson & Kent Vliet, organizers.

—Herpetological Conservation & Biology. Robert Brodman, Robert Murphy & Ben Bell, organizers.

—Biogeography of the South and South East Asian Herpetofauna. David J. Gower, organizer.

—Dendrobatoid Frog Biology. Taran Grant & Stefan Lötters, organizers.

—Ecophysiology of Reptiles. Denis Otávio Vieira de Andrade & Glenn Tattersall, organizers.

—Sequestered Defensive Compounds in Tetrapod Vertebrates and Defensive Mechanisms of Amphibians and Reptiles: Actual Knowledge and Future Perspectives. Alan H. Savitzky, Akira Mori, Deborah A. Hutchinson, & Luis Felipe Toledo, organizers.

—Status of South American Freshwater Turtles. Brian Bock, organizer.

—Development and Implementation of Recovery Programs for Endangered Chelonians. Rick Hudson, organizer.

—Conservation Genetics of Amphibians and Reptiles in the 21st Century. Robert Jehle & Trenton W. J. Garner, organizers.

All activities of the 6th World Congress of Herpetology 2008 will be held at the Hotel Tropical Conference Center, located 16 km from downtown Manaus, and 10 km from the airport, in a ritzy party area of Manaus known as Ponta Negra. The Ponta Negra Beach stretches along the high banks of the Negro River, which, at this point, enlarges to a width of 8 km. Outside the hotel complex an elevated riverside promenade with numerous bars and small restaurants provides an agreeable alternative for a late afternoon stroll in a safe atmosphere with local live music and live locals as well. You can share a privileged sight of the sunset over the Negro River.

There is a huge outdoor amphitheater where musical groups (boi, Manaus Philharmonic Orchestra, samba, pagode, etc.) perform free on Sunday afternoons and other special occasions. Because we are a special occasion, I am sure something will be happening there during your stay with us. It is too early to predict the program, but surely something lively will be happening.

The Hotel Tropical has 588 luxurious air-conditioned rooms with cable TV, minibar, telephone, and room service. The hotel has two swimming pools (one with a waterfall), a mini-shopping center, discotec (which will be open most nights), four restaurant-bars and two additional bars. The aviary, which used to occupy much of the lobby, has been transformed into a wonderful piano bar, a small zoo displaying some species of the local fauna, a botanical garden and orchid house, as well as access to the beach.

Several years ago, while on the beach at low water, a young girl walked by carrying a fresh meter-long anaconda. Frogs call from the trees, geckos scamper up walls. It is a huge, sprawling hotel with surrounding gardens and forest areas overlooking the Rio Negro! There is a security wall around the grounds, and security

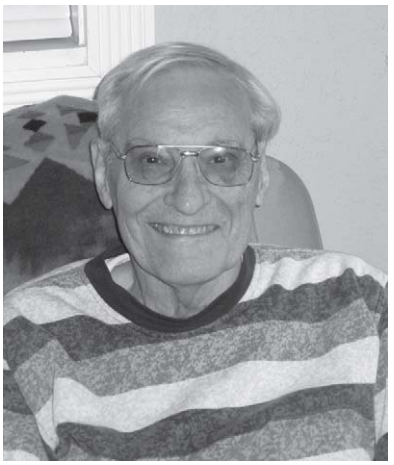
Part of the local committee aboard the Enigma to welcome all herpetologists from around the world to the 6th WCH in Manaus.

guards at the access gates, so personal safety is guaranteed and the general public does not stroll onto the grounds by any means. So it is a safe place to turn your families loose. I personally recommend all people who do not speak Portuguese to stay at this hotel. A large percentage of the wonderfully friendly hotel staff speaks English.

The food is tremendous and you are not going to waste any time traveling back and forth to the paper sessions on buses or taxis. The hotel puts out a magnificent buffet breakfast with local fruits, juices, specialty Amazonian dishes, as well as standard eggs, cereals, meats, and dairy products. As the breakfast at all of the hotels comes with the room we will NOT have second breakfast being served at coffee breaks. Coffee breaks will be high on caffeine and low on carbohydrates and calories, but do not worry as there will be munchies!

Salads,vegetables, and pasta can be found in the menus offered at the hotel restaurants, as well as native fish, seafood, beef, and fowl, all in buffet style so it is not necessary to worry about something special for your palate or diet. Most of the fruit juices served are natural and the fruit collected locally. So if you want to eat only veggies or all red meat or only nibble a bit you are your own dietician and can fill and refill your plate to your taste, I would not try to lose weight while you are here. Remember, we are in the heart of the Amazon—not on the coast, so we will have a tremendous variety of local fishes prepared in traditional recipes to experiment with. Seafood is imported from the coast, expensive, frozen, and not to be expected as part of the local cuisine. We will have some surprisingly exotic food to sample both in the daily buffets as well as in the evening socials, anti-socials, picnics, and banquets.

There is a boat dock, helicopter pad, and pontoon plane hangar at the hotel with service to the surrounding jungle lodges. Most of these jungle lodges give daily boat taxi service to Hotel Tropical. The paper sessions are in the hotel complex. Most if not all of the picnics, banquets, social activities, dance presentations, etc., will be held at the hotel, or close by, so you will use your time much more efficiently and your stay will be much less hectic if you stay here.



All other hotels are NOT within walking, running, or swimming distance from Hotel Tropical. If you prefer feeling the culture of Manaus, by all means stay at one of the smaller hotels downtown, but you will waste at least two hours a day doing so. Morning and evening shuttle buses will probably be provided, but you can also ride taxis back and forth, usually 4 people can ride for the price of the fare ($12US). There are inexpensive hotels downtown as well as youth hostels for people on a tight budget and we will run free shuttle buses to and from Hotel Tropical to downtown. Tap water is safe to drink, there is not a malaria problem at Hotel Tropical, the beer is cold, and the environment exciting to say the least. See our web site for registration material and hotel/airfare packages: www.Worldcongressofherpetology.org

See you in Manaus!

Richard C. Vogt, Director
Sixth World Congress of Herpetology-AIHA-SSAR Joint Meeting

NEWSNOTES

Herbert C. Dessauer Honored by LSU

On September 6, 2007 the Foundation for Louisiana State University Health Sciences Center added several positions to the Louisiana Board of Regents Endowed Professorship Program. Among these is the "Herbert C. Dessauer Professorship in Graduate Studies." Readers of HR will recognize Herb as a pioneer in the development of molecular systematics and the use of molecular techniques to analyze hybridization and its consequences. Herb was also the first graduate student to receive the Ph.D. from the LSU Health Sciences Center, in New Orleans, in 1952.

University of Illinois Museum of Natural History

The Illinois Natural History Survey (INHS) is pleased to announce that we are once again filling loan requests for the University of Illinois Museum of Natural History (UIMNH) Amphibian and Reptile Collection. This exceptional collection was moved to storage in 2002 because of space re-assignment by the University of Illinois. The INHS has just finished moving the entire collection to our facilities. Direct all inquiries to the curator, Chris Phillips, at chrisp@inhs.uiuc.edu. The collection is computerized and can be searched at the URL below. This search engine will return limited location data (county, state & country). Specific location information can be obtained by contacting the curator.

<www.inhs.uiuc.edu/cbd/collections/AmphReptColln/herp_links/uiherps.html>

Summer Field Course in Conservation Biology, with an Emphasis on Amphibians and Reptiles

A field course in Conservation Biology will be offered at the Lakeside Laboratory from 2–27 June 2008. Lakeside Lab is located in northwestern Iowa, along the intersection, from east to west, between the Eastern Deciduous Forest and Great Plains, and along the intersection, from north to south, between the recently glaciated Lakes Region and the older, better drained, and more variable stream systems associated with Missouri and Mississippi River uplands.

A combination laboratory and field course, Conservation Biology examines the history of the Upper Midwest from the retreat of the latest glaciers to the present day. Northwest Iowa is a land-

scape of lakes, wetlands, prairie, and oak savannah; it is also a place of intense agriculture, an area of concentrated summer tourism, and it hosts a wind farm. In this context, native ecosystems will be compared against altered ecosystems, and the processes of restoration will be measured against these extremes. Students will participate in a habitat restoration and should bring rugged clothing, sturdy boots, heavy canvas gloves, and a hard hat.

The herpetofauna of this area is well known. Highlights include the turn-of the-century (19th to 20th) commercial collections of 20 million leopard frogs/yr, the pioneering surveys of Frank Blanchard in the 1920s, and more recent findings that bear on the global problems of amphibian malformations and declines. We will visit the only known Prairie Rattlesnake populations in Iowa.

For information about Lakeside Lab see:

http://www.continuetolearn.uiowa.edu/lakesidelab/

For more information about the course, contact: Michael J. Lannoo, Indiana University School of Medicine - TH Holmstedt Hall, Rm 135, ISU Terre Haute, Indiana 47809, USA; e-mail: mlannoo@iupui.edu.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (rwh13@csufresno.edu) well in advance of the event.

10–12 April 2008—55th Annual Meeting of the Southwestern Association of Naturalists, University of Memphis, Tennessee, USA. Information: http://www.biosurvey.ou.edu/swan/

11–13 April 2008—Fourth Annual Sonoran Desert Herpetological Symposium, Tucson, Arizona, USA. Information: http://www.arts.arizona.edu/herp/

5–8 June 2008—Joint Meeting of Texas Herpetological Society, SW PARC, Horned Lizard Conservation Society; University of Texas, Austin, Texas, USA. Information: gad.perry@ttu.edu

18–21 June 2008—32nd International Herpetological Symposium; Nashville, Tennessee, USA. Information: www.kingsnake.com/ihs/

23–27 June 2008—6th Symposium on Lacertids of the Mediterranean Basin, Lesvos Island, Greece. Information: http://www.elerpe.org/

23–28 July 2008—51st Annual Meeting, Society for the Study of Amphibians and Reptiles; 88th Annual Meeting, American Society of Ichthyologists and Herpetologists; 66th Annual Meeting, The Herpetologists' League. Montreal, Quebec, Canada. Information: http://www.dce.ksu.edu/jointmeeting/

17–20 August 2008—6th World Congress of Herpetology, Manaus, Brazil (meeting jointly with SSAR). Information: http://www.worldcongressofherpetology.org/index.php?section=51

24–29 November 2008—VIII Latin-American Congress of Herpetology (VIII Congreso Latinoamericano de Herpetologia), Topes de Collantes, Sancti Spiritus, Cuba. Information: Roberto Alonso Bosch (e-mail: 8voclah@fbio.uh.cu or ralonso@ecologia.cu).

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Joshua Hale** or **Ben Lowe**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

Impacts of Invasion Stress on Invasive Cane Toads

The process of invading a novel environment may introduce new stresses to invasive species themselves, but these impacts have received little attention. While studying a Cane Toad (*Chaunus* [*Bufo*] *marinus*) invasion in the Northern Territory, Australia, the authors noticed frequent abnormalities in the spinal joints of toads at the invasion front. To determine whether the traits that facilitate successful invasion (e.g., larger body size and greater distance moved per day) are related to spinal arthritis, they examined toads from three invasive populations and established that arthritis only occurs in larger toads, and that the frequency of the condition in a population is correlated with the population's mean movement rate. Using pairs of size- and sex-matched toads that differed by spinal condition, both telemetry of free-ranging toads and locomotor performance tests showed that arthritic toads move as far and as fast as non-arthritic conspecifics. Bacterial cultures from arthritic and normal spinal joints showed that arthritic joints are infected by *Ochrobactrum anthropi*, a common soil bacterium. The authors conclude that the invasion process, which selects for larger body size and longer limb length (making animals more susceptible to degenerative disease), and a highly active lifestyle of almost constant movement (causing even greater stress on the spine), have rendered the cane toad susceptible to joint bacterial infection and spinal arthritis.

Brown, G. P., C. Shilton, B. L. Phillips, and R. Shine. 2007. Invasion, stress, and spinal arthritis in cane toads. Proceedings of the National Academy of Science 104:17698–17700.

Scent Marks Indicate Competitive Ability in Lizards

Scent marks are typically thought to be signals of an individual's competitive ability, even in that individual's absence from its territory. However, in addition to conveying information about a potential competitor in an area, these marks may also signal the resource availability of the area. To determine the role of male scent

marks in intrasexual communication in the Iberian Wall Lizard (*Podarcis hispanica*), and whether these roles change across the reproductive season, the authors captured lizards from near Valencia, Spain in the early (March) and late (June) breeding season. Ten males from each season were exposed to four experimental tests: scent marks from a stimulus male similar in size, scent marks from a larger male, scent marks from a smaller male, and no scent (control). These trials showed that early (but not late) in the breeding season, males were attracted to areas scent marked by males of similar or larger size (as measured by time spent in marked area) but not to areas marked by smaller males. These results indicate that *P. hispanica* males can obtain information on rival male size, shown to be an honest indicator of dominance in this species, from scent marks. Because males spent more time in areas marked by presumably dominant rivals, the authors suggest that scent marks may function as indirect measures of territory resource quality, assuming that dominant males defend superior territories. They also discuss potential explanations of the seasonal change in male response to scent marks.

CARAZO, P., E. FONT, AND E. DESFILIS. 2007. Chemosensory assessment of rival competitive ability and scent-mark function in a lizard, *Podarcis hispanica*. Animal Behaviour 74: 895–902.

Discrimination of Sea Turtle Artifacts Using DRIFT Spectroscopy

Sea turtle (Family Cheloniidae) scutes have been widely used in the manufacture of historic artifacts such as jewelry and furniture. Keratins from these scutes closely resemble those from bovid horn sheaths, and it is of great importance to museum curators and law enforcement officers to correctly identify the origin of artifacts, particularly given the endangered status of all sea turtle species. The authors investigated the utility of diffuse reflectance infrared Fourier transform (DRIFT) spectroscopy to distinguish between sea turtle and bovid keratin. Using 35 bovid samples from 24 species and 24 sea turtle samples from 4 species, they found that examinations using only raw DRIFT spectra may result in spurious taxonomic assignment, but analyzing these data using discriminant analysis provided reliable identification of all standards used in this study. This technique can also be used to differentiate protein-based plastics (i.e., casein) from sea turtle carapace. The authors conclude that DRIFT spectroscopy combined with discriminant analysis provides a rapid, non-destructive method of distinguishing sea turtle keratin in artifacts and may be a powerful tool in the modern wildlife trade.

Underestimation of Tropical Frog Diversity

Amphibians are rapidly declining, yet the number of amphibian species remains underestimated. Together, these observations reveal a pressing need for rapid evaluation of species richness. The authors used a combination of three methods—isolation by distance, phylogenetic analyses (to determine prevalence of paraphyletic species), and comparison of molecular distances (to determine patterns of intra- and interspecific distances)—to analyze previously published and new 16S mtDNA sequence data from 60 species of French Guianese frogs with the goal of estimating the number of undescribed species in this region. With these techniques, they calculated that the "true" number of species relative to the 60 study species is underestimated by 22–115%. They found that although geographically widespread species exist, most geographically distant populations could be considered new species, and that the many instances of paraphyletic species indicate the presence of undescribed cryptic species. From their results, the authors propose that a pairwise genetic distance of 0.03 is appropriate for distinguishing species in this group, and with this approach they identified 129 candidate species. This suggests that amphibian decline might be even more dramatic than previously thought, as both identified and unidentified species are being lost.

Hormones and Performance Capacity in Male Lizards

Males of many species advertise their quality with elaborate sexual signals, but the mechanism that links male signals and their fighting ability remains unknown. To test the hypothesis that signal size and fighting ability are related through circulating hormone levels, the authors examined adult male Green Anole lizards (*Anolis carolinensis*), a species in which dewlap (throat fan) size has been shown to predict bite force performance. They captured males during (N = 82) and after (N = 26) the breeding season in Louisiana, USA and measured their morphology, bite force, and concentrations of testosterone and corticosterone in blood. Males were classified into two previously described (presumably age-related) size classes: heavyweights and lightweights. Comparisons of the size classes revealed that heavyweights had higher testosterone levels in the breeding season than lightweights, but corticosterone levels did not differ between the groups. Also, for lightweights, but not heavyweights, testosterone levels were correlated with dewlap size and bite force, but this relationship is due to the influence of body size on all three traits. The authors conclude that these results suggest complex relationships among testosterone, morphology, and performance. They propose that smaller

males suppress testosterone levels until they reach a competitive size, when higher testosterone then increases bite force and dewlap size.

Diversification and Convergence in Desert Night Lizards

Species in the night lizard genus *Xantusia* are characterized as having high site philopatry and specific habitat requirements (e.g., individuals may spend their lives under a single log), and previous work has shown that the group has an evolutionary history of deep divergences. To test species delimitations and to compare morphological and mitochondrial assessments of phylogenetic relationships, the authors used sequence data from the mitochondrial cytochrome *b* gene (1143 bp) of 508 lizards in the *X. vigilis* species complex from 156 localities. For subsets of these lizards, they also sequenced a second mitochondrial region (ND2) and two nuclear introns (α-enolase and GAPD). Using standard Bayesian, maximum parsimony, and maximum likelihood techniques with mtDNA data, they propose a novel phylogenetic hypothesis for the *X. vigilis* group, which is largely supported by the nuclear data, and which suggests that the recognized taxonomy for this group underestimates species diversity. Their results support the conclusion that multiple species have converged on a rock-crevice-dwelling morphology, and they infer a deep history of cryptic speciation. The authors propose that vicariance in the late Miocene drove the diversification of *Xantusia*, while climate change in the Pleistocene determined their distribution.

LEAVITT, D. H., R. L. BEZY, K. A. CRANDALL, AND J. W. SITES, JR. 2007. Multi-locus DNA sequence data reveal a history of deep cryptic vicariance and habitat-driven convergence in the desert night lizard *Xantusia vigilis* species complex (Squamata: Xantusiidae). Molecular Ecology 16:4455–4481.

Environment Influences Developmental Trade-offs in Frogs

Fitness tradeoffs between size at and time to metamorphosis have been well-studied in amphibians and other taxa, and larval environmental conditions have been shown to influence these traits. However, multiple mechanisms may drive these tradeoffs. The authors tested the hypothesis that an individual's allocation of resources between growth and development in somatic versus reproductive structures may be driven by environmental conditions, a mechanistic explanation that has received little attention. To this end, they performed two experiments in which *Xenopus laevis* (African Clawed Frog) tadpoles were exposed to varying diets. In the first experiment, 5 groups of 5 tadpoles were reared communally in high or low food treatments, and one group per treatment were weighed and fixed for gonadal size measurement at approximately two week intervals. Results showed that food restriction reduced both somatic and gonadal growth rates, but not developmental rates. In the second experiment, 10 tadpoles were raised individually to metamorphosis on each of three food treatments (low, medium, and high), at which point they were weighed and fixed. These results showed that individuals that experienced food restriction had reduced somatic growth and development and smaller gonads, but the developmental stage of the male testes at metamorphosis was not affected. Together, these results suggest that the lower fecundity associated with small body size at metamorphosis may be at least partially due to gonadal size at metamorphosis, and not just reduced rates of somatic development. As habitats are continually degraded, the influence of environmental conditions on gonadal growth may be an important factor in population regulation.

MCCOY, K. A., M. W. MCCOY, A. AMICK, L. J. GUILLETTE JR., AND C. M. ST. MARY. 2007. Tradeoffs between somatic and gonadal investments during development in the African clawed frog (*Xenopus laevis*). Journal of Experimental Zoology 307A:637–646.

A Developmental Staging Series for *Anolis* Lizards

As the field of evolutionary developmental biology ("evo-devo") has emerged, the need for new model organisms for the study of morphological evolution has grown. Although there is no typical model squamate for developmental studies, lizards in the speciose genus *Anolis* have become a model system in ecology and evolution and may be useful in developmental studies as well. The relationship between morphology and ecology is well-known in this group, as many Caribbean species have independently evolved distinct morphological adaptations that allow them to exploit particular microhabitats. The authors propose that *Anolis* offer the opportunity to integrate evolutionary and developmental studies, and they present a generalized developmental staging series for the genus. They examined approximately 1000 embryos of 8 *Anolis* species, and determined *A. sagrei* to be the most appropriate model for the genus. They describe 19 morphologically distinct stages of *Anolis* embryo development from preoviposition to hatching, with close attention paid to the development of traits known to be important in anole biology (e.g., limb and toe lamellae development). The authors suggest that this staging series can provide a baseline for future studies of evo-devo in this genus.

SANGER, T. J., J. B. LOSOS, AND J. J. GIBSON-BROWN. 2007. A developmental staging series for the lizard genus *Anolis*: a new system for the integration of evolution, development, and ecology. Journal of Morphology: Early View.

Fecundity and Female-Biased Size Dimorphism

Although there are many factors that may influence the evolution of sexual size dimorphism, fecundity is thought to be one of the most important selective forces on body size. The authors tested the hypothesis that female body size influences offspring number and size in the Mountain Dragon, *Rankinia* (*Tympanocryptis*) *diemensis*, an Australian agamid lizard with pronounced female-biased size dimorphism. Over four sampling years, they captured 93 gravid females in the field and housed them until oviposition, after which they measured clutch and individual offspring characteristics. Results showed a positive relationship between female size (and condition) and clutch size, but no correlation between female size or condition and average egg mass, or between number of eggs in a clutch and average egg mass. There were also no correlations between maternal size and hatching mass or hatching success. The authors infer that the only way for female *R. diemensis* to increase their reproductive output is to have a larger body size and therefore produce a larger number of offspring (as females did not vary individual egg size), a conclusion that contributes to explaining the female-biased size dimorphism in this species.

Stuart-Smith, J., R. Swain, R. D. Stuart-Smith, and E. Wapstra. 2007. Is fecundity the ultimate cause of female-biased size dimorphism in a dragon lizard? Journal of Zoology 273:266–272.

A New Phylogeny of African Cobras

Although many phylogeographic studies of widespread sub-Saharan African mammals exist, there are no such studies of reptiles. The authors examined African spitting cobras, a group of widespread elapid snakes that occur in savanna habitats and were once considered to be a single species (*Naja nigricollis*), to test phylogenetic and biogeographic hypotheses and to investigate the evolution of spitting. They obtained samples from 81 individuals of 48 taxa and sequenced fragments of two mitochondrial regions (ND4 and cytochrome *b*) totaling 1333 bp. Using standard phylogenetic analyses (maximum parsimony, maximum likelihood, and Bayesian inference), they propose a new phylogenetic hypothesis for the group that supports the monophyly of African spitting cobras, and of Asiatic cobras (both spitting and non-spitting). Biogeographic results indicate that the radiation of African spitting cobras likely predates the radiation of large African ungulates and the Pliocene expansion of the African savanna. The authors suggest that spitting evolved three times in cobras, but cannot exclude alternative hypotheses. They also discuss additional taxonomic implications of the new phylogeny.

Wüster, W., S. Crookes, I. Ineich, Y. Mané, C. E. Pook, J. Trape, and D. G. Broadley. 2007. The phylogeny of cobras inferred from mitochondrial DNA sequences: evolution of venom spitting and the phylogeography of the African spitting cobras (Serpentes: Elapidae: *Naja migricollis* complex). Effectiveness of Coral Snake Antivenoms

Coralsnakes (Family Elapidae) occur from the southern U.S. to Argentina. Envenomations by coralsnakes are uncommon (< 2% of total snakebites), but their bites are considered serious medical emergencies, with antivenom as the main form of treatment. In the U.S., the two medically significant species of coralsnakes are *Micrurus fulvius* (Florida Coralsnake) and *M. tener* (Texas Coralsnake). In 2006, the lone producer of antivenom used for treatment of U.S. coralsnake envenomations announced that production would be discontinued, but that adequate supplies were available to meet expected needs into late 2008. In this study, Sánchez and colleagues evaluated the effectiveness of both the discontinued Wyeth antivenom (NACSA) and Coralmyn antivenom, produced by the Mexican company, Bioclon. Venom lethal doses (LD_{50}) and antivenom effective doses (ED_{50}) were determined in lab mice. Coralmyn antivenom was able to effectively neutralize LD_{50} doses from both *M. fulvius* and *M. tener*, while Wyeth antivenom only neutralized *M. fulvius* venom.

Fossil Anuran with South American Affinities Unearthed in Madagascar

Faunal connections between Madagascar and other Gondwanan land masses have long been a subject of interest for biogeographers. Comparisons of fossil dinosaur assemblages and molecular analyses on ratite birds, iguanian lizards, podocnemid turtles, and boid snakes all independently point to Madagascar having a late connection to the Indian subcontinent and South America (the later likely via Antarctica). The authors describe a large, highly ossified Late Cretaceous fossil anuran from Madagascar, rivaling in size the largest known extant (*Conraua goliath*) or extinct (*Calyptocephalella*) anurans. This anuran was placed in a newly erected genus: *Beelzebufo* (*Beel'zebul* [Greek], Devil, and *Bufo* [Latin], toad), and given the specific epithet *ampinga* ([Malagasy], shield). A suite of characters place *Beelzebufo* within the hyloid clade Ceratophryinae, a group whose extant and extinct members were previously known only from South America. This find represents the first Malagasy anuran (extant or extinct) belonging to a non-ranoid group with extant representatives. Because *Beelzebufo* appears to be nested within the clade, these results also point to an early diversification of extant Ceratophryinae (before 55 Mya) and cast doubt on the currently accepted estimates on the timing of the "main hyloid" (i.e., excluding Myobatrachidae and *Calyptocephalella*) radiation (65–55 Mya).

José M. Cei, author of landmark works on the herpetofauna of Argentina and Chile and a specialist on systematics, ecology, and biogeography, and on the chemistry of anuran skin secretions, died on 8 January 2007 in Mendoza, Argentina, at the age of 88. He was born Giuseppe Michele Alfredo Maria Cei on 23 March 1918 to a father whose early Tuscan ancestors were Greek immigrants from Ceo (Latin for Kéa or Keos, one of the Cyclades Islands in the Aegean Sea), hence the family name. His mother was a descendent of the famed 16th-century Italian, Pietro Andrea Mattioli, one of the greatest Renaissance botanists and herbalists. Cei's parents owned a business founded by his grandfather in the 1860s that produced seeds for agricultural purposes. During 1935–1939 Cei studied at the Università degli Studi di Firenze (Florence) with Nello Beccari, a comparative and neuroanatomist who specialized on amphibians and reptiles, but it was Cei's first expedition—to Ethiopia in northeastern Africa in 1939—that whetted his interest for exploration and ecology. He received his doctorate at the Università degli Studi di Pisa in 1940 and then became the equivalent of an assistant professor of zoology at Florence. His early work was on the comparative anatomy of mammals, respiration in cyclostome fishes, and sexual cycles in amphibians. It was his interest in amphibians that led him into a collegial relationship with Robert Mertens of Frankfurt am Main, then the leading European herpetologist, who became his mentor.

By 1940 World War II was well underway and Cei was mobilized by the Italian Army, first as an artillery officer in North Africa and then as an officer in the topographical service. After the Italian armistice in September 1943, Cei was held briefly by British forces, but on his release he joined Italian partisans fighting German troops in northern Italy. Eventually he was captured by the Germans. During his interrogation by a German officer, Cei learned that the officer was from Frankfurt and that, in fact, he knew of Professor Mertens. By chance, Cei still had in his pocket his last letter from Mertens, which he showed to the officer. Cei was soon released. By July 1944, Cei was working with the United States occupation forces and in 1945 returned to Florence as a teacher in courses for American soldiers organized by the American Army in Europe. Later, he decided to emigrate and, after a short research visit to Senegal, in November 1947 he arrived in Argentina where he would spend most of the rest of his life.

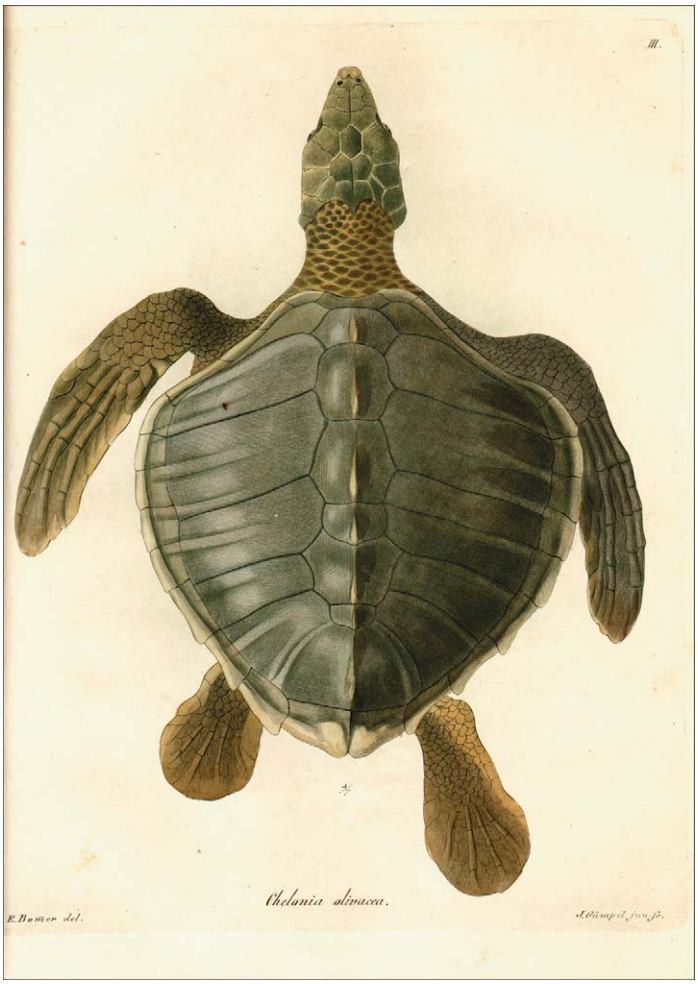
Cei was hired as a professor of biology at the Universidad Nacional de Tucumán in northwest Argentina and became a citizen in 1952. During this period he held several important posts, including director of the Institute of Biology and, later, of the Institute of General Biology and Experimental Embryology. In 1950 he was one of the founders of the university's School of Medicine. In 1955, he moved south to the Universidad Nacional de Cuyo in the state of Mendoza, on the eastern slopes of the Andes, where he served as professor in the School of Medicine and director of the Institute of Animal Biology until he retired in 1980. Throughout this period and even after retirement, Cei held visiting professorships in several countries including Angola, Chile, Italy, Portugal, and the USA. He maintained a research relationship with the Museo Regionale di Scienze Naturali in Torino (Turin) during 1986–1998 and served in several important governmental advisory posts at the state and national levels in Argentina. He was a member of the executive committee that organized the First World Congress of Herpetology, held in the UK in 1989. He became an honorary professor in the national universities at Río Cuarto in 1981, at Tucumán in 1990, and at Cuyo in 1995. In 2005, he was awarded an honorary doctorate by Argentina's Universidad de San Luis and in 2006 was honored for his life's work by the Legislature of his home state of Mendoza with the "Libertador General San Martin" prize.

His first publication (1940) was on the ferns of the Kaffa primary forest in Ethiopia. What followed was a steady stream of nearly 370 titles on fishes, amphibians, reptiles, and mammals covering diverse topics including sexual cycles, ecology, physiology, biochemistry, systematics, evolution, and biogeography. His works appeared every year, except for the war year of 1945, and he became a regular contributor to European, South American, and North American serials including *Journal of Herpetology*. For three decades he collaborated with the Italian pharmacologist, Vittorio Erspamer, at the Università degli Studia di Roma "La Sapienza" in Rome, to investigate biogenic substances isolated from the skins of frogs. Cei's use of various biochemical techniques allowed him to distinguish sibling species which led him to work in systematics beginning in the 1950s. He described nearly 50 new taxa of frogs (in the genera *Atelognathus*, *Leptodactylus*, *Odontophrynus*, *Syrrhophus* [now in *Phrynopus*], *Telmatobius*), snakes (*Atractus*, *Elapomorphus*), and lizards (*Cnemidophorus*,

Ctenoblepharis, Diplolaemus, Homonota, Phymaturus, Pristidactylus, Tropidurus, Vilcunia, and especially *Liolaemus*). Cei was particularly interested in the natural history and systematics of the reptiles of arid and semi-arid environments in South America.

He authored several books, including college-level texts on animal biogeography (1946) and general biology (1951) and a Darwin anthology (1947). He is best remembered by herpetologists for his masterful monographs on the herpetofaunas of Argentina and of Chile. His "Batracios de Chile" (1962) is the companion to Roberto Donoso-Barros's volume on Chilean reptiles (1966). "Amphibians of Argentina" was issued in 1980, with supplements in 1987 and 2001, the latter co-authored with Esteban Lavilla. Cei's massive volumes on Argentina's reptiles covered the central and southern (1986) and northern and eastern regions (1993) of the country. In 1993, he co-authored a revision of the Neotropical colubrid genus *Chironius* with two herpetologists in the United States, James Dixon and John Wiest. Cei's systematic research involved some 25 years of work with his wife, Sylvana Silvi Cei, who died in 1998 (see *Herpetological Review*, 30:202, 1999). He had travelled some 350,000 km in the field with her and, as a skilled artist, she illustrated many of his books and papers.

José Cei was a dynamic teacher and research colleague who had a broad knowledge of modern biology, which he integrated in innovative ways in his research. He trained several doctoral students, co-workers, and disciples in Argentina (Beatriz Alvarez, Francisco D. Barbieri, Francisco Bertini, Victor Bottari, Rosa Graciela Cohen, Alejandra Hernando, Nora Ibarguengoytía, Arnaldo H. Legname, A. E. Paz, Dora Rengel, José Alejandro Scolaro, Maria E. Tedesco, Fernando Videla, Jorge D. Williams) and in Portugal (Eduardo G. Crespo). Cei's enthusiastic personality and contagious love of science and life will be greatly missed by his colleagues throughout the world.



ZOO VIEW

Ridley Sea Turtle

MANY MEN DO LITTLE ELSE THAN SUPPLY THE MARKETS WITH THE MEAT AND EGGS. ACCORDING TO AN EXPERT IN THESE MATTERS, RICHARD M. KEMP, TURTLERS MOST OFTEN MAKE THEIR CAPTURES BY MEANS OF THE PEG. BITS OF THE GRASS FLOATING ABOVE THE GRAZING TURTLES BETRAY THEIR WHEREABOUT AND IF THEY ARE NOT STARTLED IT IS NOT DIFFICULT TO FASTEN THE PEG IN THE SHELL. A PEG IS AN IRON INSTRUMENT LIKE A BLUNT NAIL, TO WHICH A LINE IS ATTACHED; AND WHICH, WHEN DRIVEN INTO THE SHELL, EASILY SLIPS OUT OF THE END OF THE LONG POLE IN WHICH IT IS PLACED. BY MEANS OF THE LINE THE TURTLE IS DRAWN ON BOARD THE BOAT . . . IF A TURTLER GOING HIS ROUNDS IN THE MORNING FINDS THE TRACKS MADE ON THE WAY TO AND FROM THE NEST, HE TAKES A SHORT STICK AND CAREFULLY THRUSTS IT DOWN HERE AND THERE IN THE TRAMPLED SPACE UNTIL PUSHED THROUGH THE EGG, THE YOLK UPON THE PROBE DISCOVERS THE NEST. FOURTEEN NIGHTS LATER HE IS ON THE GROUND WAITING TIL THE CREATURE COMES ASHORE, WHEN HE TURNS HER ON HER BACK, AND IN THE MORNING CARRIES HER TO THE MARKETS. PERSONS IN THE BUSINESS CLAIM THAT THERE IS NO DIMINUTION IN NUMBERS, WHICH, IN VIEW OF THE WHOLESALE DESTRUCTION, SEEMS HARDLY POSSIBLE.

—SAMUEL GARMAN, *ON THE REPTILES AND BATRACHIANS*, 1883

Kemp's Ridley Turtle (*Thalassochelys Kempii*, now *Lepidochelys kempii*) was described by Samuel Garman in 1880 (Bull. Mus. Comp. Zool. 6[6]:123–126) using two specimens sent by Richard M. Kemp of Florida. At that time, this turtle, found in the Gulf of Mexico, was called "Bastard," because it was thought to be a cross between the Green and Loggerhead turtle. Director

The Olive Ridley Sea Turtle (*Chelonia olivacea*, now *Lepidochelys olivacea*) was described in Johann Friedrich Eschscholtz's *Atlas*, issued in five parts with lovely hand-colored plates. In this work, he described new species of amphibians and reptiles, including the sea turtle pictured here.

ESCHSCHOLTZ, J. F. 1829–1833. *Zoologischer Atlas: enthaltend Abbildungen und Beschreibungen neuer Thierarten, während des Flottcapitains v. Kotzebue zweiter Reise um die Welt, auf der russisch-kaiserlichen Kriegsschlupp Predpriaetië in den Jahren 1823-1826 / / beobachtet von Dr. Friedr. Eschscholtz . . .*
Imprint: Berlin, Gedruckt und verlegt bei G. Reimer.

Reprint of all the herpetological part from the *Atlas*; only parts I, II, and V contain material on amphibians and reptiles. Facsimile Reprints in Herpetology, No. 15. Ohio Herpetological Society, Athens, Ohio. 1966.

Patrick M. Burchfield from the Gladys Porter Zoo in Brownsville, Texas, has been involved in recovery efforts of this endangered sea turtle for the past 25 years. During that time, Burchfield has been a vital force in coordinating a joint program with the United States Fish and Wildlife Service (USFWS) and the Mexican government. He leads the U.S. portion of the Programa Binacional de la Tortuga Lora, the Binational Project by focusing on logistics, nest protection protocols, new technologies, and legal matters. He was a recipient of the USFWS Endangered Species Program's 2006 National Recovery Champion award, a prestigious honor indeed.

In a new book, *Biology and Conservation of Ridley Sea Turtles*, edited by Pamela T. Plotkin (2007, Johns Hopkins Press, Baltimore MD; ISBN-13: 978-0-8018-8611-9, ISBN-10: 0-8018-8611-2), Burchfield and two coauthors nicely summarize the recovery efforts in the chapter called "Kemp's ridley recovery: how far have we come, and where are we headed?"

Research Associate Jack Frazier from the Smithsonian's National Zoological Park Conservation and Research Center in Front Royal, Virginia, is senior author of another chapter entitled "Human-turtle interactions at sea."

Two Views of the Value of Zoos and Aquariums

For much of their history, zoos have affirmed only an imperial mastery over Nature. When operated with intelligence and compassion, however, zoos can be a most effective conservation tool. How can they best achieve this? By becoming conservation centers, by placing Nature preservation at the center of all their efforts, by reaching for the highest standards in all their projects and activities, by seeking to awake, enthrall, and educate, by articulating the wonderful benefits of conserving biological diversity, and by making strategic alliances with other cultural and natural history institutions. Zoos have the marvelous potential to develop a concerned, aware, energized, enthusiastic, caring, and sympathetic citizenry. Zoos can encourage gentleness toward all other animals and compassion for the well-being of wild places. Zoos can cultivate environmental sensitivity among their hundreds of millions of patrons. Such a populace might then want to live more lightly on the land, be more careful about using the world's natural resources, and actually to vote for politicians who care about the wild inhabitants of the earth and the health of the wild places that remain. To help save all wildlife, to work toward a healthier planet, to encourage a more sensitive populace: these are the goals for the new zoos."

—David Hancocks, *A Different Nature. The Paradoxical Work of Zoos and Their Uncertain Future*, 2001.

The zoo today is a cultural fossil, a barren evolutionary branch in the leafing of postmodernism. But it was not always so. Early on, a weak case could be made that here indeed was actual Nature, if not in the raw at least very close. Earlier zoo-goers saw the lions' fearsome teeth, felt the water buffalo's power. There was awe when the caged vulture spread its wings. Such attributes seemed real, the animals their embodiment. All it took was naïveté and a misdirected imagination after the manner of Flaubert's fictional characters Bouvard and Pécuchet. Today's zoo occupies a netherworld between real Nature, which can never be known, and a leaky bucket of cinematic "realism" that retains no secrets at all. Zoos claim to represent the first while competing actively with the second. Grasping at both, they fail to be either.

—Stephen Spotte, *Zoos and Postmodernism. Signs and Simulation*, 2006

Professionals in zoos and aquariums are faced with a multitude of critics who often ask challenging questions, the most serious of which is whether these institutions should exist at all. And if they deserve to continue, what form should they take? When these questions are generated by their colleagues with years of professional experience, it behooves the serious zoo worker to pay attention to their concerns, arguments, and conclusions.

An architect by training, David Hancocks was the director of several zoos: Woodland Park Zoo in Seattle, Washington; Arizona-Sonora Desert Museum in Tucson; and Werribee Open Range Zoo in Australia. In his writings, he has stressed the importance of naturalistic exhibits and the critical need for zoo workers to design aesthetic enclosures that appeal to both the visitor and the animals which live in these places. His book (2001; University of California Press; Berkeley; ISBN 0-520-21879-5) follows the historical evolution of zoos and aquariums throughout the world: the good, the bad, and the ugly. Overall, he stresses that much work needs to be done today to address the issues of animal welfare and conservation. Zoos and aquariums can become major forces only if enlightened and positive changes can be integrated into their missions.

Marine biologist Stephen Spotte has been director of the Aquarium of Niagara Falls, curator of the New York Aquarium, and director of Mystic Aquarium. His book (2006; Fairleigh Dickinson Press; Madison, Teaneck, New Jersey; ISBN 0-8386-4094-X) goes a step beyond Hancocks' book, for questioning whether zoos and aquariums should exist at all in their present form. His argument is unsettling: the dual purposes of education and conservation are not met in these institutions. He puts his conclusion this way, "Postmodernism is driven by images and other simulations of reality that make the exhibition of living animals passé. In shopping malls and theme parks, captive animals are transformed into their own images, becoming symbols of indirect commodification, objects of visual *flaneur*. Window shopping and a visit to the zoo have much in common."

It is easier to dismiss the views of critics outside the zoo profession but when the criticisms are generated from within our community, these harsh evaluations deserve careful scrutiny.

Bibliomania

Belin. Well; we live in a marvellous book-collecting and book-reading age—yet a word more :

Alman. I crave your pardon, Belinda ; but I have a thought which must be now imparted, or the consequences may be serious.

Lysand. I wait both your commands.

Alman. My thought—or rather the subject which now occupies my mind—is this :You have told us of the symptoms of the *Disease of Book Madness*, now pray inform us, as a tender-hearted physician, what are the *means of its cure*?

Belin. The very question I was about to put to our bibliomaniacal physician. Pray inform us what are the means of cure in this disorder?

Lysand. You should say **Probable Means of Cure**; as I verily believe that there are no certain and correct remedies.

Belin. Well, Sir ; *probable* means—if it must be so. Discourse largely and distinctly upon these.

Lysand. Briefly, and perspicuously, if you please : and thus we begin.

—Reverend Thomas Frognall Dibdin, 1811

Herpetologists throughout the ages have struggled with a seemingly incurable malady: bibliomania. Families have been torn apart, weeks spent in used bookstores, houses remodeled to accommodate more and more bookcases, and finances devastated. The condition is so severe and pervasive that a book was written about it by the Reverend Thomas Frognall Dibdin in 1811—*Bibliomania, or, Book Madness: A Bibliographical Romance, in Six Parts: Illustrated with Cuts* (Printed for the author, by J. M'Creery ..., and sold by Messrs. Longman, Hurst, Rees, Orme, and Brown).

The University of Michigan has digitized this book and it is available at http://mdp.lib.umich.edu/cgi/pt?id=39015005643682.

A lasting cure has still not been found to this day. Read *A Gentle Madness: Bibliophiles, Bibliomanes, and the Eternal Passion for Books,* by Nicholas A. Basbanes (New York, H. Holt and Co., 1995).

A Chelonian Armageddon

On 25–28 July 2007, I traveled to Atlanta, Georgia to attend the 5th Annual Symposium on Conservation and Biology of Freshwater Turtles and Tortoises, a joint annual meeting sponsored by the IUCN Turtle Survival Alliance (TSA) and IUCN Tortoise and Freshwater Turtle Specialist Group. Although I knew that the news about the continued survival of many of these creatures was problematical, I was not prepared for the constant stream of troubling papers by workers documenting pressures throughout the world, with many showing graphic images detailing the causes: habitat destruction and alteration, poaching and stockpiling of turtles and tortoises in range countries for eventual slaughter to satisfy the demand for pâté in Asia, mounds of hundreds of chelonians held in food markets, disease outbreaks, commercial turtle farming, trade in plastrons and shells for curios, and collection for the commercial pet trade. To get a sense of the scope of this catastrophe, consult IUCN Red List of Threatened Species 2006 <http://www.iucn.org/themes/ssc/redlist2006/redlist2006.htm>.

Each evening, many delegates gravitated to the nearest saloon to try and make sense about we had heard and what strategies could be employed to reverse the trend. By the end of the conference, I was nearly in shock even though organizer Rick Hudson tried to lift spirits by saying that the mission of TSA was to ensure that no chelonian became extinct during this century. It was gratifying to see that so many committed people, battling heroically against exploiters, developers, and bureaucrats, cared about the fate of terrapins, turtles, and tortoises; their efforts deserve support.

For more information on TSA activities, see 2004 *Herpetological Review* 35[2]:110 and contact Dwight Lawson (e-mail: dlawson@zooatlanta.org) or Rick Hudson (e-mail: rhudson@fortworthzoo.org), or visit the TSA website at www.turtlesurvival.org.

Biographies

Kraig Adler has written two important historical biographies of deceased biologists and their contributions to the science of herpetology: *Herpetologists of the Past, Part 1* (1989) and *Herpetologists of the Past, Part 2* (2007). In Adler's spectacular volumes, there are many references to zoos and aquariums—names of importance to the zoo community, details of the careers of people working in these places or authors writing about these institutions (Table 1). Each biography gives a sketch of the person's life with special emphasis on herpetology, references to other biographical information, the person's signature, and in almost every case their portrait. To obtain a copy of vol. 2, contact SSAR Publications Secretary Breck Bartholomew (details located inside front cover of this issue). Vol. 1 is now out of print but available on the web (www.ssarherps.org) [click on "Publications"]. Additional information may be found in Card and Murphy (2000. SSAR Herpetol. Circ. No. 27, 44 pp.) and Murphy (2007. Herpetological History of the Zoo and Aquarium World. Krieger Publ. Co., Malabar, Florida).

***** *Lineages of zoo herpetologists in the United States.*
****** *Herpetological History of the Zoo and Aquarium World.*

In the paper following, Hans-Werner Herrmann describes his exciting project in Cameroon which includes a study of the endangered Goliath Frog (*Conraua goliath*). This anuran is rarely kept in zoo collections because it is generally a delicate captive. An adult individual was successfully maintained at the Chicago Zoological Park (Brookfield Zoo) for 4 years, 4 months, and 7

days in a large semi-aquatic exhibit (Snider and Bowler 1992. SSAR Herpetol. Circ. No. 21, 40 pp.). In the mid-1960s at the Ft. Worth Zoo in Texas, late curator John Mehrtens hung wide, flexible strips from the top to the bottom of the enclosure to cover walls and exhibit glass; he said this arrangement prevented the jumping frogs from injury. From the Duisburg Zoological Garden in Germany, Gewalt (1977. Zool. Gart. [N.F.], Jena 47:161–192) covered catching, transport and keeping these frogs. Gillespie et al. (1988/1989. Proc. Amer. Assoc. Zoo Vet., p. 62) sexed Goliath Frogs by laparoscopy at the Cincinnati Zoo.

The American Association of Zoological Parks and Aquariums (AAZPA) was founded in 1924. Seventy years later, the name was changed to the Association of Zoos and Aquariums (AZA). Some of the organizational purposes of AZA are 1) to promote discussions and cooperation among zoo and aquarium professionals; 2) to set high standards for its accredited member institutions, now over 200; and 3) to support *in situ* and *ex situ* conservation initiatives. In the article below, Shelly Grow and Ruth Allard highlight the ambitious initiative by these institutions to address the issue of amphibian declines and the role that zoos and aquariums will play in 2008 to reverse this trend.

Zoo-based In-situ Herpetology: Setting Baselines in Western Cameroon

HANS-WERNER HERRMANN
Arizona Research Laboratories &
School of Natural Resources (Wildlife Conservation and Management)
University of Arizona, 1657 E. Helen Street (BIO5)
Tucson, Arizona 85721, USA
e-mail: hwh@u.arizona.edu

In 1998, when I was the curator of Herpetology, Ichthyology and Invertebrates at Cologne Zoo in Germany, I was contacted by representatives of the German branch of the American Linen Supply Company (ALSCO). The company wanted to contribute to the conservation of species and biodiversity. ALSCO Germany felt that their corporate identity would be enhanced by chameleons and that they would like to sponsor a chameleon enclosure at Cologne Zoo. After further correspondence, I realized that this could extend far beyond the common zoo practice of sponsored enclosures. Subsequently, we developed an outline for a conservation initiative sponsored by ALSCO Germany and implemented by Cologne Zoo. Chameleons were to be the flagship species for this project which in reality encompassed multiple species of amphibians and reptiles.

We eventually set our sights on Cameroon. Southwest Cameroon is one of the chameleon diversity hotspots in Africa, in particular the mountain chain known as "Dorsale Camerounaise" contains numerous montane species. We focused our attention on two areas: 1) Mt. Nlonako, a tropical rainforest mountain that reaches 1800 m in elevation situated approximately in the center of the north–south extending "Dorsale Camerounaise" and 2) Tchabal Mbabo, a mountain range at the northern limit of this mountain chain representing a humid island with cloud forests in a tropical savanna landscape.

Compared to other tropical African countries, Cameroon has received a considerable amount of herpetological attention, especially owing to the works by Swiss herpetologist J.-L. Perret and French herpetologist J.-L. Amiet, who both described a large number of new species from this area over the last 50 years. However, complete herpetofaunal inventories, quantitative surveys, and ecological studies on amphibians and reptiles are rare or lacking for large parts of Africa, including Cameroon. Baseline data from such studies constitutes the foundation on which conservation and management decisions should be based.

We started herpetofaunal inventories in 1998 at both locations, Mt. Nlonako and Tchabal Mbabo—the latter posing remarkable logistic challenges due to its remoteness and inaccessibility (Herrmann et al. 1999, 2000; Herrmann and Herrmann 1999, 2002; Kolter et al. 2001). The cooperate funding during the initial phase of the project permitted us to invite herpetologists from the Zoological Research Institute and Museum Alexander Koenig (ZFMK) in Bonn. Wolfgang Böhme and his students Oliver Euskirchen and Andreas Schmitz, who had just finished their graduate work at nearby Mt. Kupe, joined us for field work. At this time I was adjunct faculty at Philipps University in Marburg, where as a part of my teaching commitment, I gave herpetological lecture series and seminars. Some of the graduate students showed interest in fieldwork in Cameroon and joined us during several of our field trips. Later two of them, Mirco Plath and Markus Solbach, decided to conduct their graduate research on anuran communities at Mt. Nlonako (Plath 2003; Plath et al. 2004; Solbach 2003).

In 2002 I joined the Zoological Society of San Diego's Center for Reproduction of Endangered Species for a three-year field study on Goliath Frogs (*Conraua goliath)* in Cameroon. The species' distribution is limited to Cameroon and Equatorial Guinea. Goliath Frogs are under severe pressure from hunting and habitat degradation. During many long nights in rapids and around waterfalls of Cameroon's rivers, the preferred habitat of Goliath Frogs, we processed a large number of frogs, tadpoles, and eggs—which are deposited in nests on gravel banks. We used capture-recapture techniques and radiotelemetry (Figs. 1, 2) to gain insight into the species' ecology and behavior. As the number of Goliath Frogs in zoological collections is very limited, we performed morphological and anatomical studies on sexual diversity, reproductive status, stomach contents, and diet. Additionally, a large number of tissue samples were collected. These tissues are now being used in DNA-based studies on the phylogeography, population genetics, and mating systems of Goliath Frogs.

In 2003, Taylor Edwards from the University of Arizona joined us for seasonal field work. During his stay we discovered a novel type of locomotion in Goliath Frogs—"skittering"—which had previously been seen only in much smaller frogs (Herrmann and Edwards 2006). On 23 February 2003 at 0200 h, we found a pair of Goliath Frogs mating in a nest. The male measured 330 mm SVL, with a mass of 3220 g—which makes it the largest frog of this or any other living species ever documented (Fig. 3). This size is rivaled only by the recently described fossil frog *Beelzebufo ampinga* (Evans et al. 2008) which, extrapolated from skull bone fragments, may have reached SVL of > 400 mm. Does this indicate the functional size limit of the anuran body plan?

As for chameleons, which initially caught ALSCO's attention, we studied chameleon spatial distribution at Mt. Nlonako (Harbort

FIG. 1. Hans-Werner Herrmann and Taylor Edwards (right) implant a radio transmitter under field conditions into an adult Goliath Frog (*Conraua goliath*).

and Herrmann 2002) and aspects of the reproductive biology of Mountain Chameleons (*Chamaeleo montium*) (Herrmann and Herrmann 2005). Chameleons are a characteristic and relatively abundant herpetofaunal element of SW Cameroon. They are particularly attractive lizards and are in high demand in the international reptile pet trade. Large numbers are collected and exported from Cameroon. In this situation, baseline data and research on the biology of chameleons with the goal of establishing meaningful management plans is an immediate need.

FIG. 2. Field assistant Solomon Echalle crossing a river during a Goliath Frog radio tracking session.

FIG. 3. A male Goliath Frog captured on 23 February 2003 at 0200 h with a snout–vent length of 330 mm and a mass of 3220 g. Note the casting net that is used to capture the frogs.

A specimen of Sundevall's Worm Snake (*Leptotyphlops sundewalli gestri*) from the lower slopes of Mt. Kupe proved to be the second specimen recorded from Cameroon, and is a significant taxon range extension (Herrmann et al. 2004).

At the end of 2004 we concluded the detailed inventories of amphibians and reptiles at Mt. Nlonako (Herrmann, Böhme, Euskirchen et al. 2005; Herrmann, Böhme, Herrmann et al. 2005) and Tchabal Mbabo (Herrmann et al. 2007). Mt. Nlonako was established as the center for species richness for a single locality in Africa, with 93 amphibian and 63 snake species. Indeed, with regard to snake species diversity, Mt. Nlonako ranks as one of the most species-rich places in the world. Two new frog species, *Cardioglossa alsco* from Tchabal Mbabo (Herrmann et al. 2004) and *Phrynobatrachus nlonakoensis* from Mt. Nlonako (Plath et al. 2006), were discovered during our survey work.

An extensive collection of herpetological vouchers is now deposited at the Zoological Research Institute and Museum Alexander Koenig, Bonn (ZFMK), and the National Museum of Natural History, Smithsonian Institution, Washington, D.C. (USNM).

Acknowledgments.—I wish to thank Mr. Horst Nobis of ALSCO Germany for his substantial financial contribution which initiated and facilitated this endeavor. I am grateful to Cologne Zoo and the San Diego Zoological Society for additional financial support. I would like to thank the local experts, mostly Cameroonian villagers, without whom only a fraction of the amphibians and reptiles would have been found. Special thanks to my Cameroonian project field assistants Otto Mesumbe, Solomon Echalle, Bartholomew Tchiengue, and Dansala Djire. Dansala died tragically in December 2004. Taylor Edwards helped tremendously, both in the field and in the lab. Numerous discussions with Taylor inspired a multitude of new ideas. Roger Repp edited the manuscript. The Cameroonian Ministries of Scientific and Technical Research (MINREST) and Environment and Forestry (MINEF) issued research, collecting, and export permits.

Silver Spring, Maryland 20910, USA
e-mail: SGrow@aza.org

YEAR OF THE FROG: ADDING THE *EX SITU* COMMUNITY'S STRENGTHS TO CURB AMPHIBIAN EXTINCTIONS

Since its formation in 1990 and until its merger with other World Conservation Union (IUCN) amphibian conservation groups into the IUCN/Species Survival Commission (SSC) Amphibian Specialist Group (ASG) in 2006, the Declining Amphibian Population Task Force (DAPTF) led the charge to verify anecdotal reports beginning in the 1970s of drastic and global amphibian population declines and disappearances, identify target populations and regions meriting immediate attention, gather evidence concerning the causal factors contributing to amphibian population declines, set up infrastructure to facilitate long-term data collection, and to disseminate information throughout the scientific community and to the public (Heyer and Murphy 2005). In September 2005, the IUCN and Conservation International convened an Amphibian Conservation Summit in Washington, DC to devise a global strategy of action to arrest amphibian declines and extinctions (Mendelson et al. 2006). A key outcome of this meeting was the *Amphibian Conservation Action Plan* (ACAP), which was published in July 2007 (Gascon et al. 2007). Even before its final publication, researchers, land managers, zoological community professionals, and others had already started tackling the pieces for which they were responsible. Momentum continues to build as awareness about the amphibian conservation crisis grows.

The ACAP charges the global zoological community with leading *ex situ* conservation efforts, creating assurance populations for those species that would go extinct before the threats facing them could be addressed in the wild (Lips et al. 2005; Mendelson et al. 2006; Pounds et al. 2007; Young et al. 2007). *Ex situ* conservation is only one component of the much larger holistic approach of the ACAP and species that are candidates for *ex situ* conservation primarily consist of those listed as Endangered and Critically Endangered by the Global Amphibian Assessment (GAA) (IUCN et al. 2006). The *ex situ* programs are implemented by regional zoological associations: the Association of Zoos and Aquariums (AZA) in the United States, the European Association of Zoos and Aquariums (EAZA), the Australasian Regional Association of Zoological Parks and Aquaria (ARAZPA), etc. To facilitate these efforts at the international level, the IUCN's Conservation Breeding and Amphibian Specialist Groups (CBSG and ASG), and the World Association of Zoos and Aquariums (WAZA) formed the Amphibian Ark (www.amphibianark.org) (Zippel 2007a).

An additional function of Amphibian Ark is to develop and deploy a public awareness and fundraising campaign to support the *ex situ* conservation community's efforts. Effectively addressing

the amphibian conservation crisis requires rapid expansion of zoos' and aquariums' capacity to meet immediate needs and funding to support these projects into the future. Amphibian Ark has designated 2008: Year of the Frog as the umbrella for this global effort. The goal of this campaign is to ensure that the general public will understand the critical issues facing amphibian populations and support the zoological community's efforts. The Amphibian Ark coordinates the international communication and networking associated with Year of the Frog, while regional zoological associations implement the campaign and related efforts in their respective regions.

Demonstrating a Growing Commitment to Amphibian Conservation and Public Outreach: A Regional Example

AZA's Year of the Frog is an integrated campaign approved by the AZA Board of Directors and developed by a task force representing AZA's Amphibian Taxon Advisory Group (ATAG; amphibian experts in the AZA community that guide collection planning, provide strategic conservation and research direction, and strive to improve amphibian husbandry throughout the AZA community); Conservation Education (CEC), Public Relations, and Marketing committees; and AZA executive office communications and conservation department staff.

While the emphasis of AZA's Year of the Frog is on challenging zoos and aquariums to expand or develop *ex situ* conservation initiatives, the campaign also encourages zoos and aquariums to support complementary *in situ* conservation efforts, develop capacity internationally, address local amphibian conservation through monitoring, surveying, research, partnering with local government agencies, advocacy, and to engage their 157 million visitors to build popular support for amphibian conservation.

The AZA Year of the Frog task force facilitates public engagement opportunities. The CEC has gathered, reviewed, culled and edited existing resources, and has created new amphibian education and outreach materials that focus on encouraging positive conservation impacts. They have also worked with the ATAG to develop fact sheets to inform visitors, docents, and staff about amphibians, population declines, the zoological community's response, and what visitors can do to help amphibians. The task force has developed campaign graphics and other items for widespread distribution, including a public service announcement that can be personalized for each participating zoo or aquarium's market. These materials, customized for a North American audience but also consistent with the global Amphibian Ark effort, are available free of charge to AZA members and the general public through the AZA Web site (www.aza.org/yearofthefrog).

The task force is also responsible for publicizing AZA members' amphibian conservation efforts within the zoological community and to a larger public audience. Articles for zoo and aquarium member magazines regarding amphibian declines and the zoological community's response have been generated, press releases have been circulated, and communication continues with well-known popular media outlets. For the campaign year, each monthly edition of the AZA member magazine *Connect* features an amphibian conservation-related story and the March 2008 edition will be devoted entirely to amphibian conservation. The general public can visit the AZA Web site and become "Friends of Frogs" by joining a grassroots advocacy network that will be contacted regarding regional and national opportunities for action. AZA zoos and aquariums will launch Year of the Frog on Leap Day, 29 February 2008, will use amphibian themes at their annual Party for the Planet on and/or around Earth Day (22 April 2008), and will also incorporate amphibian themes in their year-round education programming.

As amphibian experts for the AZA community, the ATAG provides strategic direction and shares expertise. In July 2007, the Fort Worth Zoo hosted a meeting where the ATAG identified amphibian species in Canada, the United States, Mexico, and the Caribbean whose populations would most benefit from *ex situ* conservation programs. Meeting participants included members of the ATAG steering committee and its advisory committee, staff from Amphibian Ark, and university scientists. The group utilized a prioritization tool developed by the Amphibian Ark that incorporates the species' conservation status, threats, the potential for mitigating these threats in the wild, phylogenetic uniqueness, social and scientific value, and other key variables. The group examined over 200 species listed by the GAA as Critically Endangered, Endangered, Data Deficient, or listed under the US Endangered Species Act. The resulting priority rankings are subject to change as new information and management processes are implemented, but in the meantime, provide much-needed direction for next steps. Programs to protect species outside of the US will be developed in collaboration with local experts, international zoological colleagues, and the Amphibian Ark, while programs within the US will complement state and federal priorities. The priorities, a description of the process used, and an analysis of current AZA amphibian collections and capacity (staffing, space, etc.) are included in the *Action Plan for* Ex Situ *Amphibian Conservation in the AZA Community* report (Crump and Grow 2007). The Action Plan was modeled deliberately after the *ARAZPA Amphibian Action Plan* published in June 2007 (Gillespie et al. 2007), so that zoological community capacity can be compared and evaluated internationally.

In addition to the Action Plan, the ATAG published the *Amphibian Conservation Resource Manual* in September 2007 with AZA staff support (Grow and Poole 2007). The Resource Manual is designed to help zoos and aquariums incorporate amphibian conservation into their institutional collection and master plans, create holistic *in situ* and *ex situ* conservation and research projects, build biosecure amphibian holding facilities, identify funding resources to support amphibian efforts, and develop programs for those species that would most benefit from *ex situ* conservation programs. The ATAG has also produced an *Amphibian Husbandry Resource Guide* so that AZA members can expand their staff skillsets and can respond appropriately to the conservation crisis (Poole and Grow 2008). When working with endangered species, there is little room for error, so all of these tools are designed to build capacity and expertise.

Perhaps the most important component of the Year of the Frog campaign is the infusion of AZA's significant and growing amphibian conservation efforts with a sense of urgency. AZA recognizes that the rapid and widespread declines in amphibian populations present a conservation challenge unlike any other faced by humans (Stuart et al. 2004). The Association is responding by dedicating more resources and attention to amphibians now than it has ever committed to any one taxonomic group in the organization's

history. For example, the Board of Directors created a conservation biologist position at the AZA office dedicated exclusively to amphibian conservation. Since 2004, the AZA Board of Regents has held an annual training course in *Amphibian Biology and Management*. In 2007, the Board of Regents offered this course twice to meet unprecedented student demand, thanks in large part to the generosity of volunteer instructors and the Toledo Zoo, which hosted both sessions. Because the April 2008 course filled by late 2007, it is likely that arrangements will be made to offer the course twice in 2008 as well. Tight budgets have been stretched to fund travel expenses for key meetings to expand amphibian conservation partnerships and every department at the AZA office has been engaged in Year of the Frog efforts.

The AZA community is expanding Year of the Frog beyond the zoological sector by engaging appropriate government entities in the campaign as well. At the national level, AZA's government affairs department is working with U.S. Congressional staff to support amphibian conservation, and at the local level, AZA members are engaging their public in local development projects affecting amphibian habitat and inviting civic officials to help launch and participate in Year of the Frog. Members are also reaching out to other local partners, such as parks, museums, and schools, to celebrate the Year of the Frog.

Year of the Frog Expectations

2008: Year of the Frog activities will raise the profile and the level of public support for amphibian conservation efforts. The Year of the Frog will also feature significant fundraising efforts. Already, the AZA has developed an amphibian-specific funding process that has received significant contributions from private individuals and companies. International and collaborative fundraising efforts, such as those led by the Emerging Wildlife Conservation Leaders program (EWCL; a collaborative effort sponsored by Defenders of Wildlife, U.S. Fish and Wildlife Service (FWS), and White Oak Conservation Center/Howard Gilman Foundation), the ATAG small grants program, Project Golden Frog/ Atelopus Conservation Trust (Zippel 2002), and Amphibian Ark are also underway.

Conservation success requires a long-term commitment and, as demonstrated by long-term participation in amphibian Species Survival Plans® (see next section for more detail), AZA facilities are dedicated to these efforts. 2008 will see the expansion of existing amphibian programs to both increase population sizes and include additional facilities. It will also welcome the laying of groundwork for additional programs that may not come online until after 2008. The Year of the Frog conservation goals are to lay the foundation for long-term amphibian conservation action and to garner institutional commitments so that these programs can grow over the next several years. Successful programs will not sprout immediately, but many new efforts will begin to take shape in 2008.

Partnerships are a key element to amphibian conservation success. The first 2008 edition of FWS' *Endangered Species Bulletin* periodical will be dedicated to amphibian issues, and approximately half of the articles will come from AZA-accredited zoos and aquariums. AZA members are increasingly engaging with Partners in Amphibian and Reptile Conservation (PARC), and each regional PARC network has been challenged to develop collaborative activities with local zoos and aquariums and to celebrate Year of the Frog at its 2008 meetings and events. Three AZA-accredited zoos and aquariums, the Columbus Zoo and Aquarium, Phoenix Zoo, and Houston Zoo, supported PARC's recent symposium, "Amphibian Decline and Chytridiomycosis: Translating Science into Urgent Action." Staff from fifteen zoos and aquariums and the AZA executive office participated in the meeting. The EWCL program has committed to raise funds so that AZA member Africam Safari in Mexico can expand its amphibian conservation work. AZA is helping EWCL with its fundraising and public outreach efforts. AZA is also growing its international partnerships, working with the Amphibian Ark and the Zoo Conservation Outreach Group (ZCOG) to train and support the work of international colleagues, utilizing internationally consistent prioritization processes, and sharing resources, information, and Year of the Frog campaign strategies.

Collaborative Conservation: A History of Commitment

AZA-accredited zoos and aquariums are already an active force in amphibian conservation (Wiese and Hutchins 1994; Zippel 2007b). Since 2000, AZA members have spent more than $1.1 million on amphibian conservation and research projects in more than 20 countries around the world. Two amphibian species, the Puerto Rican Crested Toad (*Peltophryne lemur*) and Wyoming Toad (*Anaxyrus baxteri*)[1] are already part of AZA's Species Survival Plan® (SSP) program (Fig. 1). The first amphibian SSP program was approved in 1984, focusing on the Puerto Rican Crested Toad (Johnson 1994). In 2007, more than 20 AZA-accredited zoos and aquariums continue to hold, breed, and provide animals for reintroduction at three sites in Puerto Rico. The program is far larger than its *ex situ* components: AZA members have developed extensive education and outreach programs that incorporate local folklore, passions, and interests, have helped create and maintain new toad habitat and have developed partnerships with government, academic, and other stakeholders throughout Puerto Rico. The second amphibian flagship program, the Wyoming Toad SSP, was approved in 1996. Listed by the GAA as Extinct in the Wild, nine AZA facilities continued to hold, breed, and reintroduce animals in 2007, in collaboration with other breeding facilities, the Wyoming Game and Fish Department, and the FWS. Causes of the population crash in the mid-1970s were unknown for decades, but the proximate cause of decline has now been attributed to the fungus *Batrachochytrium dendrobatidis* (*Bd*), complicating the rearing and reintroduction program (Johnson 1994; Odum and Corn 2005; Stebbins and Cohen 1995). Both of these SSP programs are fairly well known, in part due to their longevity and collaborative nature; however, other amphibian conservation efforts at AZA zoos and aquariums may be less familiar. The following program descriptions offer a sampling of what AZA institutions are currently doing and demonstrate the expertise and enthusiasm AZA institutions have for long-term amphibian conservation action.

Zoo staff were among the key players in discovering the novel pathogen, *Bd*, and the effect it was having on amphibians (Nichols 2003). In 1991, Dr. Donald K. Nichols took on a position as a pathologist at the National Zoological Park (NZP), following his experience as a resident there and as a pathologist at the National Institute of Health. He had consulted with zoos and universities throughout the country and in 1991 received the bodies of three

FIG. 1. The first amphibian AZA Species Survival Plan was approved for the Puerto Rican Crested Toad (*Peltophryne lemur*) in 1984. Photo courtesy of John Kast, Fort Worth Zoo.

FIG. 2. The Toledo Zoo and Bronx Zoo (Wildlife Conservation Society) house the only known surviving Kihansi Spray Toads (*Nectophrynoides asperginis)* and are developing plans in collaboration with international colleagues and the Tanzanian government to reintroduce this species to Tanzania in the future. Photo courtesy of R. Andrew Odum, Toledo Zoo.

preserved California Arroyo Toads (*Anaxyrus californicus*)[2]. The toads came from a captive colony whose population had declined 60% in just a few months; an unknown skin disease was responsible for their demise. Dr. Nichols reviewed amphibian pathology files from the NZP collection and saw evidence of the same disease. Over the next several years, clues surfaced indicating that a chytrid fungus might be involved; however, no chytrids had ever been recognized as pathogens in vertebrates at that time. In 1996, a new outbreak of the disease affected the National Zoo's collection. The zoo's resident pathologist at the time, Dr. Allan Pessier, and Dr. Nichols were able to locate and send fresh skin samples to one of the few chytrid experts in the world, Dr. Joyce Longcore. Dr. Longcore identified the fungus as not just a new chytrid species, but also as a previously unknown genus. The organism was eventually named *Batrachochytrium dendrobatidis*, meaning "frog chytrid of dendrobatids" (Longcore et al. 1999). While the organism was being identified, researchers in Central America and Australia began reporting identical situations in the field. While unable to culture the organisms, they had also identified the organisms as chytrids and Longcore later confirmed them as the same species (Berger et al. 1998; Nichols 2003). Zoological facilities continue to have an important role to play in efforts to prevent *Bd* from spreading between captive facilities and in trade, monitoring the disease, participating in captive-breeding and reintroduction programs, and limiting the impact of the disease on wild amphibian populations (Young et al. 2007).

Combining *in situ* and *ex situ* work, in 2000 the Bronx Zoo brought 500 Kihansi Spray Toads (*Nectophrynoides asperginis*) from Tanzania to US zoos when their habitat came under threat from the development of a dam (Krajick 2006) (Fig. 2). This transfer turned out to be extremely fortunate as the entire population collapsed in 2003. The timing of the crash coincided with the completion of the dam's construction and related changes to the ecosystem, the brief opening of floodgates to flush sediments, and the first observation of the fungus *Bd* in the habitat (Krajick 2006). Today, the sole surviving Kihansi Spray Toads live at the Toledo and Bronx Zoos. In May 2007, AZA members from the Bronx, Toledo, and San Diego zoos met with government and World Bank officials, facilitators from the IUCN's Conservation Breeding Specialist Group (CBSG), and other scientists to complete a Population and Habitat Viability Assessment and develop a long-range strategy to reintroduce the spray toad back to Tanzania.

Based on predictions made by Lips et al. (2006) on the rate that *Bd* was moving through Panama and its potential impacts, biologists from Zoo Atlanta and the Atlanta Botanical Garden knew that the devastating fungus *Bd* was rapidly approaching a hotspot of amphibian diversity in that country's central region (Norris 2007). Based on its location, elevation, and species assemblages (Lips et al. 2005), *Bd* was expected to take a high toll on its amphibian populations. Working with others in Panama and building on partnerships developed through Project Golden Frog (Zippel 2002), these researchers spearheaded an effort in 2005 to evacuate hundreds of frogs representing 35 species from central Panama in an effort to protect them from this devastating disease (Mendelson and Gagliardo 2005; Gagliardo et al., *in press*). The Houston Zoo and El Nispero Zoo (Panama) began constructing the first in-country, dedicated facility for maintaining critically threatened amphibians locally (Fig. 3). More than two dozen AZA facilities have supported the construction, training, and operations costs of this facility. The *Bd* fungus reached El Valle in early 2006 and wild amphibian populations began to plummet. While held temporarily at the Hotel Campestre as building construction was completed, today many of the species decimated by the arrival of *Bd* can still be found in assurance populations in the US and at El Valle Amphibian Conservation Center (Fig. 4). In 2007, the Houston Zoo was awarded a grant from the AZA Conservation Endowment Fund (CEF) to continue to support this Center and expand its outreach efforts in each of the partnering zoos and aquariums in North America.

FIG. 3. Jorge Garcia from Panama's Autoridad Nacional del Ambiente (ANAM) helps transfer Panamanian Golden Frogs (*Atelopus zeteki*) from temporary quarters to the El Valle Amphibian Conservation Center. Photo courtesy of Bill Konstant, Houston Zoo.

In the southwestern United States, AZA institutions participate in government-led ranid conservation projects. In the mountains of California, the Critically Endangered Mountain Yellow-legged Frog (*Rana muscosa*) has a limited and disjointed range (Fig. 5). Introduced trout have long been a threat to the eggs and tadpoles of this species in parts of its range and the removal of the trout has led to growth in populations of the frogs (Knapp and Matthews 2000; Vredenburg 2004). As a result, the U.S. Geological Survey (USGS) and the FWS developed a plan to remove these predators from the Angeles National Forest north of Los Angeles and zookeepers from the Los Angeles Zoo and Fresno Chaffee Zoo provided assistance in the field. The San Diego Zoo's center for Conservation and Research for Endangered Species (CRES) is currently safeguarding frogs rescued by government agencies from drying streambed pools in the San Jacinto Mountains. Once drought conditions have passed, zoo staff will work with state and federal agencies to return these individuals to their natural habitat (Bradley, *in press*).

The Santa Barbara Zoo works with the U.S. Forest Service (USFS) to survey streams in the Los Padres National Forest for California Red-legged Frogs (*Rana draytonii*) and the California Arroyo Toad (*Anaxyrus californicus*). In addition to surveying and recording ambient conditions and developmental stages when egg

masses are located, zoo staff place exclosures around the mass to prevent aquatic predators, especially the introduced Bullfrogs (*Lithobates catesbeianus*)[3] and Mosquitofish (*Gambusia affinis*), from consuming them (Foster et al. 2007). The Zoo is currently developing an exhibit that will feature reptiles and amphibians native to the Los Padres National Forest, and estimate that up to 450,000 visitors annually will learn about local herpetofaunal con-

FIG. 5. Several zoos and aquariums are supporting government-led recovery efforts on behalf of the Mountain Yellow-legged Frog (*Rana muscosa*) in the western United States. Photo courtesy of Jeff Lemm, San Diego Zoo's Center for Conservation and Research for Endangered Species (CRES).

servation through this exhibit, in addition to visitors that hear about these efforts through zookeeper talks and presentations, signage at the Zoo, and through the Zoo's newsletter (Foster et al. 2007).

In Arizona and New Mexico, ranid conservation at AZA facilities includes leopard and Tarahumara frogs. The Phoenix Zoo has been part of the Ramsey Canyon Leopard Frog Conservation Team (RCLFCT), a partnership of state and federal agencies and private groups for ten years. The Arizona-Sonora Desert Museum (ASDM) is also part of the Team. The Team's goal is to halt population declines of the Ramsey Canyon Leopard Frog (*Rana chiricahuensis*)[4]. Because of high mortality rates in the wild for eggs and small tadpoles, the team decided to rear egg masses collected in the wild at the zoo and museum, and delayed release until they had developed into large tadpoles or small frogs, life stages with higher survival rates. As a result of these reintroductions and translocations, the number of ponds where Ramsey Canyon Leopard Frogs have become or are becoming established has increased four-fold (Sprankle, *in press*). The Fort Worth Zoo headstarts Chiricahua Leopard Frogs (*R. chiricahuensis* from locales other than Ramsey Canyon) in close collaboration with the FWS, New Mexico Game and Fish Department, Arizona Game and Fish Department, and Turner Endangered Species Fund (Garrett 2006). Adult populations are brought to the Zoo for breeding purposes and the resulting tadpoles are returned to the field for repatriation.

ASDM also works with Tarahumara Frogs (*Lithobates tarahumarae*)[5]. The Tarahumara Frog's historical range included southern Arizona and northwest Mexico, but the last US Tarahumara Frog was found dead in Arizona in 1983; at least three of the last local extirpations were a result of *Bd* (Hale et al. 2005). Collaborative efforts involving two nations, two states, numerous state and federal agencies, universities, private landowners, and interested citizens have led to the collection of founder individuals in Mexico, captive rearing of these founders at ASDM, surveys of historical habitat, assessment of population responses to *Bd*, and in 2004–2006, reintroductions of the Tarahumara Frog in Arizona. While re-establishment of the species in the United States continues to face many challenges, so far, the animals are persisting and breeding in Arizona once again (Johnson 2007).

AZA efforts are not focused exclusively on frogs and toads. In the central and eastern United States, survey evidence suggests that Hellbender salamander populations of both subspecies (*Cryptobranchus alleganiensis alleganiensis* and *C. a. bishopi*) are declining throughout their ranges in the U.S. Southeast and Appalachian regions. Surveys from Missouri and Ohio suggest population declines of ca. 80% over the past few decades and a skewing of populations towards older and larger animals, indicating low recruitment into the populations (Briggler et al. 2007; Lipps 2007). Staff and volunteers from zoos and aquariums throughout the salamander's range have begun surveying and monitoring local populations in the wild. The North Carolina Zoo works with the state's Wildlife Resource Commission to monitor populations and collect water quality and population data, and in 2007 received CEF funds to expand this effort. In Ohio, AZA member The Wilds is creating a stream on-grounds to mimic Hellbender habitat with the hope of eventually housing Hellbenders and studying the reasons behind their decline. While captive animals have not yet reproduced in captivity, in October 2007, a female Hellbender laid eggs at an indoor facility at the Saint Louis Zoo. The males did not fertilize the clutch, but this landmark event was significant to those developing protocols for rearing this species in captivity. The Columbus Zoo and Aquarium, Fort Worth Zoo, Lincoln Park Zoo, Louisville Zoo, Nashville Zoo, National Aquarium in Baltimore, Oglebay's Good Zoo, Omaha's Henry Doorly Zoo, Pittsburgh Zoo and PPG Aquarium, Smithsonian National Zoological Park, and Wonders of Wildlife are all involved in Hellbender conservation as well.

Further north in Canada, the Toronto Zoo has taken an ecosystem approach to amphibian conservation. In partnership with Environment Canada, the Toronto Zoo developed an Adopt-A-Pond program in 1991 (Sealock 2005). The goal of this program is to address declining amphibian populations by providing teachers, students, and community groups with informational resources and educational opportunities to conserve, restore, and create wetland habitats. Through its FrogWatch program, people of all ages are taught to monitor local frog populations by listening for their calls and reporting their observational data to a central database. Their publication *The Urban Outback* (http://www.torontozoo.com/adoptapond/) provides technical information to homeowners for small-scale wetland restoration and includes sections dedicated to amphibians. Full curricula and complementary resource networks, such as the Zoo's Pond Guardian initiative, have been developed around these successful programs. The Toronto Zoo is a leader in promoting backyard conservation and putting international conservation issues into a familiar and local context.

Finally, throughout the AZA community, facilities are committing millions of dollars to expand their amphibian conservation capacity. The largest of these efforts will take place at the Fort Worth Zoo, where leaders have committed $18 million to build a new herpetarium. The new facility, dubbed Museum of Living Art (MOLA), will include spacious, humidity-controlled exhibits and state-of-the-art conservation tools, such as quarantine rooms and hibernacula that support the breeding of rare, endangered, and critically endangered amphibians. Both the Jacksonville Zoo and Toledo Zoo are utilizing existing space at their facilities to create additional amphibian conservation and exhibit space, while Omaha's Henry Doorly Zoo is increasing their amount of biosecure space to accommodate increasing numbers of endangered and critically endangered amphibian species.

Greater Than the Sum of its Parts: An Unprecedented Campaign

2008: Year of the Frog is a campaign unlike any other in the zoological community. Participation in the campaign is global. The campaign responds directly to an urgent conservation need. It focuses on a taxonomic group not generally given the spotlight at zoological facilities. It is fully integrated to include herpetologists, zoological veterinarians and epidemiologists, nutritionists and invertebrate specialists, small population biologists, educators, public relations departments, and marketers. It promises to raise public awareness so that 600 million annual zoo visitors worldwide understand and support amphibian conservation. The Year of the Frog campaign will raise money and attention so these programs can continue to grow in the future, even if the spotlight may shift to other taxonomic groups. And it promises to fulfill the *ex situ* recommendations outlined in the IUCN's *Amphibian Conservation Action Plan* (ACAP). The implementation of the campaign will

also provide support and participation to other components of the ACAP, making this campaign vital to the overall success of the ACAP.

This campaign is larger than the zoological community, and appropriately so. To halt amphibian declines, commitments and action must also be larger than the zoological community or any other single organization or interest group. Join us in this campaign and work together with your local zoos and aquariums to help this effort be unprecedented in its integration and ultimately, unprecedented in its success.

Guide to Acronyms

ACAP – Amphibian Conservation Action Plan
ARAZPA – Australasian Regional Association of Zoological Parks and Aquaria
ASG – Amphibian Specialist Group
ASDM – Arizona-Sonora Desert Museum
ATAG – Amphibian Taxon Advisory Group
AZA – Association of Zoos and Aquariums
Bd - Batrachochytrium dendrobatidis
CBSG – Conservation Breeding Specialist Group
CEC – Conservation Education Committee
CEF – Conservation Endowment Fund
CRES – Conservation and Research for Endangered Species
DAPTF – Declining Amphibian Populations Task Force
EAZA – European Association of Zoos and Aquariums
EWCL –Emerging Wildlife Conservation Leaders
FWS – U.S. Fish and Wildlife Service
GAA – Global Amphibian Assessment
IUCN – World Conservation Union
MOLA – Museum of Living Art
NZP – National Zoological Park
PARC – Partners in Amphibian and Reptile Conservation
RCLFCT – Ramsey Canyon Leopard Frog Conservation Team
SSC – Species Survival Commission
SSP – Species Survival Plan
USFS – U.S. Forest Service
USGS – U.S. Geological Survey
WAZA – World Association of Zoos and Aquariums
ZCOG – Zoo Conservation Outreach Group

Acknowledgments.—We wish to thank Diane Barber (Fort Worth Zoo), Lesley Dickie (Amphibian Ark/Zoological Society of London), Kris Vehrs, Paul Boyle, and Steve Feldman (AZA), and James Murphy (Smithsonian National Zoological Park) for their assistance with the development of this manuscript. We would also like to thank John Kast (Fort Worth Zoo), Bill Konstant (Houston Zoo), Jeff Lemm (San Diego Zoo's CRES), and R. Andrew Odum (Toledo Zoo) for the use of their photos and Jennifer Pramuk (Bronx Zoo) for her help with taxonomic questions. Finally, our gratitude goes out to all of the global zoos and aquariums involved in amphibian conservation, including the many facilities whose efforts were not mentioned specifically in this article.

The Global Crisis

Addressing the amphibian extinction crisis curently represents one of the greatest species conservation challenge in the history of humanity. The Global Amphibian Assessment (Stuart et al. 2004) revealed that one third to one half of the world's 6000 amphibian species are threatened with extinction. This is significantly more than any other group of organisms: by comparison, 12% of bird species and 23% of mammal species are threatened. As many as 165 amphibian species have already disappeared in recent years. This qualifies as a mass extinction event, and deserves special attention for reasons of ethics and also because amphibians deliver substantial goods and services to their ecosystems and to humans (e.g., biomedicines). The amphibian crisis has taught us a valuable lesson in that 20 years of monitoring, research, and conservation action have advanced our state of knowledge of the situation, but these efforts have failed to prevent numerous extinctions in places such as Australia, Puerto Rico, Costa Rica, and Ecuador. This sends the message that "business as usual" in terms of research and conservation, while remaining crucial, are insufficient by themselves to confront this crisis (Mendelson et al. 2006).

The Amphibian Conservation Action Plan

The myriad intertwined factors likely affecting amphibian declines and extinctions require novel, cross-disciplinary approaches to research and conservation. In September 2005, the IUCN and Conservation International convened an Amphibian Conservation Summit in Washington, DC. The world's amphibian authorities from academia, zoos, government, veterinary medicine, and other diverse disciplines gathered to conceptualize a global Amphibian Conservation Action Plan (ACAP, Gascon et al. 2007), outlining general responses required in the fields of research, assessment, conservation, and rapid responses to stem widespread global amphibian extinctions. The entire ACAP may be downloaded from the website of the IUCN-SSC Amphibian Specialist Group (www.amphibians.org).

The ACAP emphasizes basic research targeted at the underlying causes of amphibian declines, specifically highlighting diseases, climate change, and environmental contamination. The

The Lemur Leaf Frog *Hylomantis* (= *Phyllomedusa*) *lemur* is listed by IUCN as Endangered across its entire range in Costa Rica, Panama, and Colombia. Its current status in the wild appears to continue to decline as populations in Panama are being sequentially impacted by epidemics of amphibian chytridiomycosis. Following guidelines laid out by the Amphibian Conservation Action Plan and the Amphibian Ark, this species is currently well established in ex-situ populations in USA, UK, Costa Rica, and Panama and in-situ efforts are ongoing in Costa Rica. Progeny from the captive colonies are now forming the basis for basic academic studies on chytridiomycosis. Photo by Ron Holt/Courtesy Atlanta Botanical Garden.

ACAP calls for aggressive field efforts to refine our knowledge of amphibian diversity (phylogeny and taxonomy), distributions, and conservation status, in order to continuously update the Global Amphibian Assessment (www.globalamphibians.org). Conservation programs must address important long-term objectives in habitat protection, while also managing the difficult arenas of reintroductions and control of harvest. Finally, the ACAP delegation agreed that there are a number of examples in the wild where rapid-response interventions might be necessary. Such programs are to include capacity for responding to impending crises related to habitat loss, contamination, or disease outbreak, and also establishing a globally organized program to maintain captive survival assurance populations. Captive populations may represent short- or long-

term temporary solutions to prevent extinctions, while necessary research and conservation programs work to address the primary threats. They also should represent phylogenetically diverse groups for important research programs (e.g., evolution of resistance to emerging infectious diseases). These captive programs fall under the auspices of the newly launched Amphibian Ark (Pavajeau et al., *in press*; see below).

Despite substantial progress in recent years in understanding the underlying causes of the amphibian crisis, significant research gaps remain. Examples include:

- what are the effects of long-term sub-lethal exposure to environmental contaminants?
- are there direct cause-effect linkages between climate and disease?
- how exactly does chytridiomycosis kill amphibians?
- how and why are some species more affected by certain threats than are others?
- how is chytridiomycosis spread, and does the pathogen have a resting stage?
- can we design bioreserves to protect against invasive species, emerging infectious diseases, contaminants, and climate change?

These projects, among many others, will require significant time, effort, and resources before their results can be applied in any meaningful way to conserve amphibians. These questions will also require truly cross-disciplinary approaches, if we are to have any hope of identifying and responding to the potential synergistic effects between the various documented threats to amphibians. Using the ACAP as an outline, the specific role of the IUCN/SSC Amphibian Specialist Group is to support a holistic approach to the amphibian crisis that includes complementary efforts among *in situ* and *ex situ* conservation programs, basic research, and related issues of policy, law, ethics, and public education.

A Call to Action for Conservation Research

Academic institutions are the centers for much of the basic research necessary to inform conservation programs. Never has the connection between basic research and conservation been more imperative than in the present amphibian crisis. Mendelson et al. (2006) opined that the status quo approach of programs of research-as-usual and conservation-as-usual are insufficient to confront this crisis. The basic problem in this case is that conservationists, land-managers, and other stakeholders literally do not know how to implement conservation programs in the face of threats as global and pervasive as emerging infectious disease and climate change. Thus, synthetic programs must be coordinated among the research institutions globally, in order to discover the science underlying the current threats to amphibian biodiversity. This research must take place against a backdrop of continued vigilance of programs to protect habitat, prevent overexploitation, and other "familiar" threats to biodiversity. However, basic research takes time, and recent history has demonstrated that the passage of time correlates with additional amphibian extinctions. Thus, while researchers work to answer basic questions relevant to amphibian conservation (e.g., "Does amphibian chytrid fungus persist in the environment, in the absence of amphibians?") their results may come too late to save some species. Thus the clarion call was sounded to bolster such research programs contemporaneously with ambitious conservation programs (Gascon et al. 2007; Mendelson et al. 2006).

There have been a number of world-class amphibian research programs and facilities at universities and museums (e.g., Kluge 1996; Myers 2000; Trueb and Duellman 1996) that have framed our understanding of amphibian biology, and also our fundamental skills for maintaining and breeding certain species in captivity (e.g., Cullum and Justus 1973; Nace 1968; Nace et al. 1974). Nevertheless, these programs historically have tended to function in isolation from ongoing conservation programs—in fact, the focus was never on conservation. Fortunately, however, the recent call for integrated research and conservation programs comes as some such programs already exist (see below).

Model Programs

Environmental Contaminants

MICHELLE BOONE
Miami University, e-mail: boonemd@muohio.edu

Contaminants are both accidentally and purposefully released into the environment and can move through local, regional, and global cycles that result in widespread chemical exposure in both protected and human-dominated landscapes. Therefore, understanding how contaminants can influence population dynamics and community regulation is of great importance, particularly in light of worldwide amphibian population declines. Additionally, contaminants could also play a key role in amphibian declines by interacting with other stressors present in the environment, such as disease pathogens. While traditionally, toxicology has focused on lethal concentrations in simple systems in the laboratory, it is critical to integrate effects found in the laboratory with those in the field to gain better predictive power for population and community level consequences of contaminants in nature.

A group of scientists working in the field of ecotoxicology has been examining the effects of contaminants from the laboratory to field mesocosms to artificial wetlands to the natural environment, which has allowed us to explore the ecological ramifications of chemical exposure to the aquatic and terrestrial environment (reviewed in Boone and James 2005). For instance, our work with expected environmental concentrations of the insecticide carbaryl has allowed us to examine how carbaryl's toxicity was influenced by competition, predation, and pond hydroperiod across experimental venues (reviewed in Boone and Bridges 2003; Boone et al. 2004). These studies are among the first to examine how natural environmental factors can alter toxicity. From initial studies, it became clear that environmental factors influence and modify the effect of a contaminant on amphibians, that species are differentially susceptible to contaminants, and that the indirect effects of the contaminants (e.g., altering predator communities and food resources) are potentially more important than direct effects (Boone and Bridges 2003; Mills and Semlitsch 2004). We have also manipulated factors associated with chemical application, such as multiple contaminant exposures through larval development (reviewed in Boone and Bridges 2003) and exposure to chemical mixtures (reviewed in Boone and James 2005; Boone et al. 2007). These studies suggest that mimicking contaminant application through multiple exposures during larval development can stimulate larval development and lead to precocious metamorphosis.

Additionally, multiple contaminants can result in interactions that are not predictable from single factor studies. In this respect, these studies have directly addressed the question of "multiple stressors" and set the stage for evaluating ecological questions related to contaminants in natural environments that other researchers have and could follow.

The benefit of an approach evaluating effects of select contaminants in complex experimental environments (rather than broader testing of different contaminants in the simple laboratory or field conditions) is that it addresses relevant ecological questions and evaluates how contaminant effects may change or manifest themselves outside of traditional types of tests used for federal regulation. Currently, we do not understand the ecological effects of the major classes of chemical contaminants and we are only beginning to explore how other factors mediate the contaminants' effects. Although there is evidence suggesting that contaminants may play a role in amphibian population declines (e.g., Davidson et al. 2002), the mechanism is not clear. There is accumulating evidence indicating that contaminants play a role in the incidence of limb malformation through increased susceptibility to trematodes (Johnson and Chase 2004) and can decrease immune response (Christin et al. 2003; Gilbertson et al. 2003). Such studies suggest that presence of contaminants in combination with other factors could contribute to declines. Contaminants are present in the environment, and for this reason evaluating their effects, which can alter community structure and population dynamics, is of paramount importance.

Diseases

KAREN R. LIPS
Southern Illinois University, e-mail: klips@zoology.siu.edu

JOSEPH R. MENDELSON III
Zoo Atlanta, e-mail: jmendelson@zooatlanta.org

Infectious disease is now acknowledged as a major threat to amphibian populations and species at a growing number of sites around the world (Daszak et al. 2003; Stuart et al. 2004; Lips et al. 2006; Ron 2005). While amphibian chytridiomycosis has been the focus of the majority of investigations in recent years, other pathogens (e.g., ranaviruses) must also be considered (see review by Daszak et al. 2003). Along with studies related to climate change (see below), it appears that the relative novelty of disease as a direct threat to biodiversity has effectively instigated a number of innovative collaborative projects that represent basic research related to disease or pathogens, but within an explicit framework of amphibian conservation (e.g., Carey et al. 2006; Harris et al. 2006; Kriger and Hero 2007; Lips et al. 2006; Rachowicz and Vredenburg 2004; Rollins-Smith et al. 2002; Wilcox 2006; Woodhams et al. 2007). Furthermore, cross-disciplinary research and conservation programs are coming to exist, such as the Endangered Frog Research Centre at Griffith University, the Amphibian Diseases Research Group at James Cook University (both in Queensland, Australia), the Integrated Research and Challenges in Environmental Biology amphibian disease group (based at Arizona State University, USA), the Latin American RANA organization, and the recently formed international Amphibian Ecotoxicology Consortium. While many more such projects and programs are needed, the evident synthesis of research and conservation priorities does bode well for amphibian biodiversity.

A key to the innovative nature and ultimate productivity of such cross-disciplinary programs is their culture of meeting and collaborating, rather than the more traditional approach of research labs around the world working independently and thus competing with one another, whether it be implicitly or explicitly so. Within such networks graduate students, for example, may have open access to expertise that that is beyond the scope of their base institution or advisory committee. This type of access to advice and training effectively ensures future generations of researchers with a broad array of skills, professional experience, and key contacts across disciplines. Similarly, international collaborations build a culture of trust that can simplify layers of bureaucracy, to allow better focus on the science at hand and improve diplomatic relations among academics across regions.

Climate Change

SANTIAGO R. RON
Museo de Zoología, Pontificia Universidad Católica del Ecuador
e-mail: srron@puce.edu.ec

An increasing number of studies show a correlation between amphibian population declines and climate change (e.g., Blaustein et al. 2003; Pounds et al. 2006). Climate change could produce population declines either directly (e.g., by reducing the area of distribution of the species' fundamental niche; Thomas et al. 2004) or indirectly by interacting with other risk factors. The most widely studied hypothesis for the role of climate change is known as the climate-linked epidemic hypothesis (Harvell et al. 2002; Pounds et al. 2006), which posits that declines are a consequence of synergisms between pathogens and novel climate conditions. A recently proposed variant is the chytrid thermal optimum hypothesis, which posits a link between climate change and population declines attributable to chytridiomycosis (Bosch et al. 2006; Pounds et al. 2006).

The available evidence suggests that research on the effects of climate change could be crucial to develop realistic conservation programs for amphibians. Future efforts should be directed to explore the link, if any, between climate change and population declines in a more diverse array of taxa and on a larger number of regions with emphasis in biodiversity hotspots. Because the association between climate change and disease does not necessarily imply causation, there is an urgent need to test the climate-linked epidemic hypothesis by acquiring a better understanding of how climate influences the immune response of amphibians and the survival rates, virulence, and transmission of pathogens. Climate change has been linked to disease outbreaks involving more than one pathogen at a single population (Di Rosa et al. 2007) suggesting that research should test interactions with a broad array of potential pathogenic agents.

Although there are numerous studies documenting distributional shifts as a the result of climate change (for a review see Parmesan 2006), there are surprisingly few published reports for amphibians (e.g., Seimon et al. 2007). It is expected that species with restricted ranges inhabiting polar regions and mountaintops will experience severe range contractions, population declines and extinctions (Parmesan 2006). Thus, future efforts should also focus on assessing how climate change is impacting distribution

ranges, especially in tropical mountains, the regions of greatest amphibian diversity.

Global warming is unlikely to weaken in the short term. A more complete baseline dataset on how climate influences disease spread and outbreaks will allow development of predictive models to forecast regions and taxa that are likely to become threatened by climate change.

The Amphibian Ark

Although the only place to truly conserve wildlife is in the wild, *in-situ* threats sometimes cannot be mitigated quickly enough to prevent extirpation or extinction. Even with timely protection from threats under our immediate control, such as habitat destruction and over-collection, we cannot protect wild populations from threats whose effects would continue long after the immediate cause has ceased, e.g., introduced diseases, climate change, and pollution. In cases where *in-situ* threats cannot be mitigated quickly, as appears to be the case for many of amphibian species, *ex-situ* intervention is the only option to prevent immediate extinction. The IUCN has urged that "All Critically Endangered and Extinct in the Wild taxa should be subject to *ex situ* management to ensure recovery of wild populations." (IUCN 2002). Comparable calls to action are included in the Global Amphibian Assessment, the ACAP, and other IUCN documents. In response to this challenge, the World Association of Zoos and Aquariums, the IUCN/SSC Conservation Breeding Specialist Group, and the IUCN/SSC Amphibian Specialist Group have jointly formed the Amphibian Ark (www.AmphibianArk.org, Pavajeau et al. in press)**,** to guide short-term *ex situ* management to help ensure long-term survival in nature of amphibian taxa for which adequate protection in the wild is not currently possible. The AArk will facilitate coordination of *ex situ* programs implemented by partners around the world, with the first emphasis on programs within the range countries of the species, and with a constant attention to our obligation to link *ex situ* conservation measures with complementary *in situ* programs. The AArk will lead a 2008 globally coordinated, zoo-based awareness and capital campaign, 'Year of the Frog' (www.2008YearoftheFrog.org) to help zoos raise the funds to support rapidly developing programs for *ex situ* rescue efforts, *in situ* conservation, research, and communication about the amphibian extinction crisis. The goal of AArk is to prevent the anticipated extinction of hundreds of species (*sensu* Stuart et al. 2004), and to buy time for these species while ongoing basic research and conservation programs develop effective long-term measures to restore and protect populations in the wild. The program will accomplish this goal primarily by developing capacity globally to provide amphibian species with care and protection when needed, and by forming effective partnerships between *ex situ* and *in situ* components of conservation. This framework will provide a model for responding to future species conservation crises.

A Call to Action for Conservation Breeding

Ex situ management for conservation is not just a job for zoos, aquariums, and botanic gardens. Currently there is not enough capacity among these institutions to meet the needs of most of the amphibian species that require help. We estimate that the global zoo community can currently manage viable populations of ~50 amphibian species, which amounts to perhaps 10% of those requiring *ex-situ* intervention. If we are to understand the needs and requirements of the diverse amphibian species that will need help, and which by the very nature of their vulnerability are likely to be specialized, it will be important to acknowledge the valuable contribution academic institutions and individuals can provide. In an effort to increase global capacity, and also harness the skills of such specialists, the AArk must include the expertise and facilities of universities, natural history museums, and the private sector. Several existing programs serve as models in this arena.

Model Programs

Pontificia Universidad Católica in Quito, Ecuador

LUIS A. COLOMA
e-mail: lcoloma@puce.edu.ec

The Ecuadorian amphibian fauna comprise 464 described species, plus an estimated 270 awaiting discovery and/or description (Coloma et al. 2007). This fauna is not only one of the most diverse on the planet, but one the most threatened. Threats such as global warming, pathogens, and habitat destruction are magnified in this country. For example, mean temperatures in the Andes are increasing at least twice as fast as the mean global temperature (Merino-Viteri et al. 2005; Ron et al. 2003), pathogens are widespread in the Andean region (Merino-Viteri et al. 2005; Ron and Merino 2000), and the national deforestation rate (about half a million acres per year) is among the tenth highest in the world (CLIRSEN 2006). Most recent estimates indicate that at least 141 Ecuadorian amphibian species are threatened with extinction, with 5–25 presumably already extinct (updated from the Global Amphibian Assessment, IUCN et al. 2004); 84% of the threatened species live in the Andean Region. These numbers could be underestimated because at least 131 additional species are classified Data Deficient. It is expected that the number of threatened species will increase with further data.

The potential to have great losses or gains in the conservation of amphibians depends on immediate actions. Under these circumstances, Pontificia Universidad Católica del Ecuador (PUCE) is implementing the Project "Balsa de los Sapos" (Life raft for frogs), which includes a Strategic Plan for the Conservation of the Ecuadorian Amphibians in Risk of Extinction. Goals and activities within this initiative follow major guidelines of the global strategy for conservation of amphibians and the ACAP (Gascon et al. 2007). Thus, the Strategic Plan includes five major programs that are complementary to each other: 1) monitoring and research of native amphibians; 2) improvement of local capacities; 3) *ex-situ* management of all endangered species; 4) environmental education and public awareness; and 5) bioinformatics and diffusion of information. Diverse research laboratories of PUCE and its Museum of Zoology (QCAZ) have converged towards this ambitious project and several activities are already underway. Among them, PUCE raised awareness about the importance of amphibians and their crisis through a public amphibian exhibit "Sapari," carried out in Quito in 2005, which was attended by 105,000 visitors in 90 days. As well, PUCE is building capacity and initiating breeding programs for amphibians. A pilot center (with seed support of the Saint Louis Zoo) has been established for research,

management, and *ex-situ* conservation of some species, such as the surviving species of *Atelopus* (i.e., *A. exiguus, A. elegans, A. palmatus, A. spumarius, A.* sp.) and around a dozen species of Andean and Chocoan frogs under high risk of extinction. More information on this Ecuadorian "Life-Raft" initiative is available at AmphibiaWebEcuador (2006).

Manchester University, England

ANDREW GRAY
e-mail: andrew.r.gray@manchester.ac.uk

At Manchester University's Museum, an important and specialized collection of Costa Rican anuran species is being professionally and demographically managed. Although unusual to find such a conservation-focused live collection in a museum, the level of animal care and commitment Manchester is providing also fulfils many aspects of the institution's key objectives. Increasingly, museums are considered to have to play an important role in delivering some of societies global responsibilities. Endeavoring to put something real back to the planet through their amphibian conservation work allows Manchester Museum to do this in a very powerful and meaningful way. The development of global academic links and the support and involvement with 'in country' initiatives further validates this. Large captive colonies for several selected species form a backbone to the successful captive breeding programs that have been initiated here and, apart from having the benefit of a multi-disciplined team of scientists on the doorstep, the collection forms part of a valuable educational and research resource. Many students conduct non-invasive behavioral and biological projects in the department and are also directly involved in supporting conservation efforts through fieldwork.

Amphibian Research Centre in Australia

GERRY MARANTELLI

Established by Gerry Marantelli in 1994, the ARC is a self-funded private facility dedicated to conservation management, research, and education for Australian anurans. The ARC currently holds one of the largest amphibian collections in the world and is involved with ten Nationally Endangered frog species (e.g., Hunter et al. 1999). Management activities also include pioneering work with hygiene and automation: in December 2004 the ARC hosted a workshop "Captivity, Reintroduction and Disease Control Technologies for Amphibians," from which the presentations are available online at the ARC website (www.frogs.org.au). Research efforts include work on assisted reproductive technologies, cryopreservation, and control of introduced Cane Toads. ARC was involved in the discovery of the amphibian chytrid (Berger et al. 1998) and subsequent research on its biology (Berger et al. 2004, 2005; Marantelli et al. 2004), diagnostics (Berger et al. 2002), and treatment (Woodhams et al. 2003). The ARC also focuses on public education through activities like school group tours, classroom tadpole projects, and housing the community outreach Victorian Frog Group. The ARC website is one of the largest and most popular frog websites in the world with over 1.5 million total hits and 80–100,000 visitors each month. ARC work is funded through corporate and private sponsorships, government threatened species recovery programs, and through sales of captive-bred pet frogs of common native species, live food items and other hobbyist supplies, and popular frog-related items.

Concluding Comments

The ACAP is an outline of proposed programs and priorities to work towards a synthetic research and conservation program to amphibian conservation. It is not a detailed plan of action, complete with tasks and funding assigned to specific labs and persons. Sadly, such critical details and organization must await remarkably ambitious and successful fundraising programs (e.g., 2008 Year of the Frog, and proposed activities by the Amphibian Specialist Group). In the meantime, however, inaction is not acceptable and we put forward that the questions and initiatives outlined in ACAP and in various Amphibian Ark documents offer a broad menu of academic honors thesis, dissertation, and post-graduate topics, as well as questions and challenges tractable to zoos, aquariums, botanical gardens, and natural history museums of all sizes.

Biphasic Oviposition by Northwestern Salamanders (*Ambystoma gracile*) in the Cascade Mountains of Southern Washington, USA

JAMES G. MACCRACKEN

Longview, Washington 98632, USA
e-mail: jgmaccracken@longviewtimber.com

Little has been published about temporal patterns of oviposition by Northwestern Salamanders (*Ambystoma gracile*), either within or among years. Timing of oviposition can be critical to reproductive success and thus subject to strong selection pressures (*sensu* Resetarits 1996). In unpredictable, variable environments more than one tactic may be successful and evolutionarily stable. In this paper, I report the results of a four-year study that documented biphasic oviposition patterns of a population of Northwestern Salamanders, with a preliminary assessment of potential explanatory factors. Five hypotheses follow that may explain this pattern based on the effects of weather on breeding activity, or variation in breeding among different population cohorts. These hypotheses are neither exhaustive nor mutually exclusive. Testable predictions are provided for the first three, but I did not collect data relevant to the latter hypotheses.

H_1: interrupted rainfall.—Breeding in many pond-breeding amphibians appears linked to rainfall and temperature (Anderson 1967; Chadwick et al. 2006; Greenberg and Tanner 2004; Palis 1997; Semlitsch 1985; Sexton et al. 1990; Todd and Winne 2006). A period of either little or no rainfall (which is also often cooler) bracketed by wet and warm weather could interrupt breeding immigrations of Northwestern Salamanders resulting in two distinct oviposition bouts by metamorphic adults within a season. A prediction of this hypothesis is that the appearance of new egg masses is strongly positively correlated (r 0.7) with rainfall. In addition, cloudless dry periods also produce low night temperatures and the number of new egg masses should also be positively correlated with minimum air temperatures.

H_2: periodic drought.—Early breeders may have increased reproductive success during drought years because declining water levels over the summer favor earlier hatching, thus avoiding desiccation of embryos. In addition, larvae of early breeders go through metamorphosis earlier and avoid death due to complete pond drying. Furthermore, larvae of early breeders have more time to feed and develop prior to their first winter. During wetter years, late oviposition may serve to insure that embryos are not subject to late spring freezes, avoid periods of high water flow that could displace egg masses during spring run-off, and reduce exposure of embryos to predators (MacCracken 2007) through accelerated development associated with higher water temperatures later in the season (Brown 1976). Thus, periodic drought at a frequency less than the average individual life span would maintain cohorts of early and late breeders resulting in two peaks in oviposition within a breeding season.

For the advantages of early breeding to be realized: 1) oviposition should begin earlier as drought results in a shallow snowpack, early snowmelt, and relatively warm temperatures; 2) the active oviposition period should be shorter; and 3) the majority of egg masses should be deposited earlier compared to non-drought years because late breeders experience unfavorable weather during immigration.

H_3: paedomorph/metamorph.—Life history variation may result in two distinct oviposition bouts in some ambystomatid salamanders. Earlier breeding of 6–8 weeks by paedomorph versus metamorph Mole Salamanders (*A. talpoideum*) has been documented (Krenz and Sever 1995; Scott 1993; Whiteman and Semlitsch 2005). In addition, paedomorphs breed, and presumably, deposit eggs at greater water depths (Whiteman and Semlitsch 2005). Many Northwestern Salamander populations also contain both morphologies (Carl and Cowan 1945; Eagleson 1976; Efford and Mathias 1969; Snyder 1956; Sprules 1974), as did the population I studied. Contrary to the pattern reported for *A. talpoideum*, Richter and Kerr (2001) found no difference in oviposition chronology for paedomorphic and metamorphic Northwestern Salamanders, but did find that egg masses were deposited at greater depths by paedomorphs. A prediction of this hypothesis is that the peak in the number of new egg masses observed between early and late periods should be several weeks apart. In addition, the number of new egg masses should be nearly equal between early and late oviposition periods, because the proportion of paedomorphs in Northwestern Salamander populations increases with elevation (Carl and Cowan 1945; Eagelson 1976; Snyder 1956) and given the moderate elevation of my study area, I would expect the size of the two cohorts to be close to unity.

H_4: alternate year breeding.—Some ambystomatids have alternate (or more) year breeding (Church et al. 2007; Harris and Ludwig 2004; Kinkead and Otis 2007; Nussbaum et al. 1983), suggesting that resources may not be sufficient to support annual breeding by all individuals in a population. Alternate year breeders may reproduce later in the season because limited resources result in a longer period for ova to complete the yolking stage. For this scenario to produce two oviposition bouts, populations would have to contain both bi-annual and annual breeders.

H_5: double clutching.—Double-clutching also could produce two distinct periods of oviposition within a breeding season. Northwestern Salamanders are presumed to only lay one egg mass/season (Thoms et al. 1997), and this assertion likely rests with the physiological improbability of double-clutching. However, the lack of documentation prevents dismissing this hypothesis.

Methods.—This study was conducted in a 25.5-ha wetland in the Cascade Range of southwestern Washington, USA. The wetland had a southeast aspect, 3% slope, an elevation range of 915–940 m, and had over 40 ponds of various sizes (see MacCracken 2007) and in various stages of vegetation succession. MacCracken (2005, 2007) provided a more detailed description of the study area. Snow normally begins accumulating in late-November/early-December and persists until late March/early June. Rainfall is generally greatest in April–June, followed by a summer drought beginning in mid-July and persisting until September–October.

Thirty-three ponds consistently used for breeding by Northwestern Salamanders were surveyed annually from 1999–2002 (MacCracken 2007). I surveyed each pond every 5–7 days starting with the onset of Northwestern Salamander oviposition activity (early April–early May) until all egg masses had completely hatched, typically in mid-August. I searched each pond for egg masses by traversing the perimeter, and wading sections 1.3 m deep that were not visible from the shore. Water clarity allowed good visibility to a depth of about 2 m. When an egg mass was first discovered, I marked each with a numbered pin flag inserted into the substrate next to the egg mass, and measured the depth of the top of the egg mass below the water surface with a meter stick (MacCracken 2007).

Data on air temperature and precipitation were collected from 2–4 sites at each visit, except in 2000. Weather stations were established in the north and south portions of the wetland in 1999 with two more stations added in 2001 at intermediate locations. Each station had two rain gauges about 50 m apart and a maximum-minimum thermometer placed in a shaded location between the rain gauges. Instruments were set at ground level and read and reset at each visit. In addition, water temperature of each pond was measured with a liquid thermometer about 12 cm below the surface at each visit. These data allow for an assessment of hypotheses one, two, and three as outlined below.

For H_1, Spearman rank-order correlations were estimated comparing weekly rainfall and minimum air temperature with the number of new egg masses for 1999, 2001, and 2002.

For H_2, mean total rainfall and snow water equivalent for 1998–2006 water years (October–September) was calculated from data for the South Fork Bull Run Snotel station (15 km SE of my study area, 902 m elev., http://www.or.nrcs.usda.gov/snow/data/historic.html). The mean of these metrics were compared to the individual water year data for 1999–2002 to identify drought years during my study. The date of the onset of oviposition and the duration of the active oviposition period was compared between drought and non-drought years. The mean number of new egg masses laid between the early and late oviposition periods was compared with a Mann-Whitney *U*-test as the data were slightly skewed in some years (Fig. 1). Early and late periods were delineated based on the date of the fewest number of new egg masses observed following the initial peak.

For H_3, the mean number of new egg masses was compared between early and late periods with a Mann-Whitney *U*-test. Furthermore, paedomorphs of Northwestern Salamanders oviposit at greater water depths (Richter and Kerr 2001), thus early deposited egg masses should be at greater depths than late deposited egg masses. Mean egg mass depth was compared between early and late periods with a Mann-Whitney *U*-test as these data were also slightly skewed toward smaller values.

Results.—I observed a total of 762 egg masses during this study, with the greatest number in 2001. The temporal distribution of oviposition had two peaks each year (Fig. 1).

To examine H_1, rainfall data from the study area were available for each year except 2000. In 1999, 2001, and 2002, 1–5 weeks of either little or no rainfall, bracketed by wetter weather, occurred during the active oviposition period (Fig. 1). The strongest positive correlations between number of new egg masses and weekly rainfall occurred in 2001 ($r_s = 0.75$, $P = 0.05$) and 1999 ($r_s = 0.49$, $P = 0.13$; Fig. 1). However, the relationship was negative and weak in 2002 ($r_s = -0.19$, $P = 0.37$). There was a lag of about a week between the occurrence of new egg masses and rain in 2002. When that lag effect was removed, the correlation was moderate and positive ($r_s = 0.65$, $P = 0.09$). In addition, the strongest correlation between new egg masses and minimum air temperatures was for 2001 ($r_s = -0.67$, $P = 0.06$), but was in the opposite direction of that predicted. These comparisons provide mixed support for the interrupted rainfall hypothesis.

Relative to H_2, the winter of 2000–2001 experienced a strong El Niño event. Precipitation for the 2001 water year was 65% of normal; the snowpack was shallow, ephemeral, and had melted completely by mid-March on the study area (MacCracken, pers. obs.). The average January–April 2001 snowpack at the South Bull Run station had less water content (1.5[SE = 0.8] cm) than the average for 1998–2005 (5.8[1.0] cm).

Both average water and maximum air temperatures on the study area were 3° and 7°C warmer, respectively, in May 2001 than other years, despite May and June rainfall in 2001 being 145% and 35% greater than the same months in 1999 and 2002, respectively (Table 1). Oviposition by Northwestern Salamanders began 1–3 weeks earlier in 2001 compared to 1999, 2000, and 2002 (Fig. 1). Duration of the active oviposition period in 2001 was six weeks compared to 7–9 weeks for the other years. In addition, more egg masses were deposited during the early than late period in 2001, a pattern that was reversed in the other years (Fig. 1). These comparisons agree with the predictions of the periodic drought hypothesis.

For H_3, an average of 3.2(0.1) weeks separated the peaks between the early and late oviposition periods (Fig. 1). However, on average 22% fewer new egg masses were deposited during the early period (76[32]) when compared to the late period (93[18], $U = 8.0$, $P = 1.0$) over the four years of study. In addition, the average depth of egg masses below the water surface was 25(1) and 23(1) cm ($U = 63849$, $P = 0.01$) for early and late periods, respectively. This result was not a function of pond drying as water levels were stable during this time period (J. G. MacCracken, unpubl. data). These comparisons are consistent with the predictions of the paedomorph/metamorph hypothesis (H_3).

Discussion.—None of the hypotheses examined can be dismissed based on my analyses and are best viewed in the context of Chamberlin's (1965) method of multiple working hypotheses in that several mechanisms may act in concert (Elliott and Brook

FIG. 1. Counts of new *Ambystoma gracile* egg masses and average rainfall and minimum daily air temperature by 10-day increments for 1999–2002 in the Cascade Mountains of southwestern Washington, USA. Rainfall and air temperature data were not collected in 2000.

2007) to produce the pattern I observed. Furthermore, additional relevant hypotheses also may be developed in the future.

Given the caveat above, my analyses and those in the published literature lend the greatest support to the two weather-related hypotheses as explanations for biphasic oviposition by Northwestern Salamanders. At the seasonal level, numerous studies of a variety of amphibians have found two or more waves of immigrations to breeding ponds that corresponded to precipitation, air temperatures, or both (Anderson 1967; Beneski et al. 1986; Brodman 1995; Chadwick et al. 2006; Cook et al. 2006; Greenberg and Tanner 2004, 2005; Harris 1980; Healy 1975; Hurlbert 1969; Loredo and Van Vuren 1996; Palis 1997; Semlitsch 1981, 1985; Sexton et al. 1990; Timm et al. 2007; Todd and Winne 2006; Vasconcelos and Calhoun 2004). The weight of evidence from these studies lends strong support to the interrupted rainfall hypothesis, despite the relatively inconclusive results from this study, suggesting that: 1) Northwestern Salamanders might use other clues to initiate immigration, (e.g., declining barometric pressure); 2) that my sampling regime was temporally too coarse to capture the details of the relationship; 3) the occurrence of rain may be more important than the actual amount; or 4) paedomorphs make up a relatively large portion of the population.

My data lend some support to the periodic drought hypothesis as a mechanism sustaining two oviposition bouts. The response

by Northwestern Salamanders to drought conditions during the winter of 2000–2001 may provide insight into the effects of climate change on this species. If increased frequency of drought is part of climate change (see Lueng et al. 2004 and Payne et al. 2004) then a pattern similar to that observed in 2001 also may occur more frequently. Precipitation amount and timing are likely the most important variables (Russell et al. 2005; Todd and Winne 2006). Warm winter/early-spring temperatures with adequate rainfall will favor early breeding. Chadwick et al. (2006) speculated that earlier breeding by *Triturus* spp. could increase reproductive success by: 1) increasing the length of time larvae have to feed before the next winter; 2) reducing the age at first breeding; 3) reducing competition with other larval amphibians; and 4) creating greater temporal separation between growing larvae and size-limited predators. However, these advantages will be realized only if ponds maintain adequate water levels, which is less likely during drought years.

The paedomorph/metamorph hypothesis also was weakly supported by the data. However, the prediction of equal numbers of egg masses being laid in early and late periods was based on my assumption that the paedomorph and metamorph cohorts were equal in size, and the prediction could also be consistent with the interrupted rainfall and periodic drought hypotheses. In addition, although the 2-cm difference in egg mass average depth between early and late periods was statistically significant, its biological significance is questionable. Furthermore, my findings both conflict and agree with Richter and Kerr (2001) who reported no temporal separation in oviposition, but a 5-cm difference in egg mass depth between the two morphologies in an experimentally manipulated Northwestern Salamander population in Washington. The temporal discrepancy could be due to differences in study areas, the experimental nature of Richter and Kerr (2001), or other unknown factors. Again, the biological significance of a 2–5-cm difference in egg mass depth is unknown. Surveys designed to quantify breeding activity of the two morphologies are needed to provide better information about the veracity of the paedomorph/metamorph hypothesis.

In summary, biphasic oviposition occurred in each of four years, with the temporal properties apparently influenced by seasonal and annual rainfall patterns and to a lesser degree by average minimum temperatures. A droughty winter followed by a wet spring resulted in an earlier and shorter oviposition period with more egg masses in the early peak; which was the opposite of wetter years. Although my data are consistent with predictions of the hypothesis that the biphasic pattern was a result of differential breeding by paedomorphs and metamorphs, the assumptions behind those predictions need validation.

Acknowledgments.—A. DeYoung, E. Smith, and S. Lampman assisted in data collection. Comments by M. P. Hayes, A. J. Kroll, K. O. Richter, and anonymous reviewers improved this paper. This research was conducted under annual renewal of Washington Department of Fish and Wildlife Scientific Collection Permits.

The Common Kingsnake (*Lampropeltis getula*), distributed across much of the United States (Ernst and Ernst 2003) and inhabiting numerous habitats in the Southeast (Ernst and Ernst 2003; Gibbons and Semlitsch 1991; Means 2006), was historically a common member of Florida's snake communities (Krysko and Smith 2005). However, kingsnake populations have declined statewide, and many appear to have been locally extirpated (Krysko and Smith 2005). This decline has generated concern among conservationists, and speculation as to potential causes ranges from habitat loss, road mortality, and pollution, to collection for the pet trade (Ernst and Ernst 2003; Krysko 2002; Krysko and Smith 2005). Further ecological research including population monitoring is needed to enhance conservation efforts (Krysko 2002; Krysko and Smith 2005). Here, we examine long-term population trends of the eastern kingsnake (*L. g. getula*) in northern Florida and southern Georgia by comparing data from two studies conducted more than two decades apart.

Methods.—Tall Timbers Research Station (TTRS), Pebble Hill (PH), and the Wade Tract (WT), all located in the Red Hills of northern Georgia and southern Florida, served as the study sites. The Red Hills region lies between Tallahassee, Florida, and Thomasville, Georgia, and is bounded by the Ochlockonee River to the west and the Aucilla River to the east. TTRS is the southernmost site and is located ca. 30 km (20 miles) N of Tallahassee, Florida. The landscape, characterized by a rolling topography and rich clay soils, is dominated by open pine forests interspersed with hardwood bottomland drains and annually harrowed fields. The Red Hills region is intensively managed for Northern Bobwhite (*Colinus virginianus*) and other Longleaf Pine (*Pinus palustris*) associated species (Stoddard 1931). Management focuses on the maintenance of open upland habitats via prescribed burning and mechanical methods to inhibit hardwood encroachment and maintain herbaceous groundcover.

The initial study took place at TTRS from May 1976 to July 1983. Snakes were opportunistically collected during the daytime as we obtained radiotelemetry fixes for the Eastern Diamondback Rattlesnake (Means 1985), searching for Cottonmouths (Cook

1983), or conducting other field activities. Individuals were marked via scute clipping (Brown and Parker 1976) and basic biological data were obtained (Cook 1983; Means 2005).

During 2002–2005, an intensive study using a systematic trapping protocol on TTRS, PH, and WT reexamined the Red Hill's snake community. Snakes were captured with drift fences used in conjunction with box traps (D. Richardson, pers. comm.; Burgdorf et al. 2005), and single-ended funnel traps (Fitch 1987) were set at the end of each of the four fence arms. Fences were placed randomly across the landscape in bottomland hardwood drains, a forested "buffer" zone bordering hardwood drains, upland pine forests, and fields. Twenty-four fences were set at TTRS and PH for at least 11 days per month from March to October, 2002. In 2003, trapping effort was increased and standardized, with 42 fences set for 18 trap days per month from March to October at TTRS, PH, and WT. Thirty-six fences were set at TTRS and PH during 2004–2005 using a trapping protocol identical to 2003. Additional snakes were collected via opportunistic encounters by individuals conducting other research activities. Snakes were initially marked either via a passive integrated transponder (PIT) tag or via a unique scute clip.

Results and Discussion.—Methodological differences between the two studies prohibit rigorous statistical comparison of the data sets. However, the large change in detection of the Eastern Kingsnake is striking. During the initial 7-year study, 119 nonvenomous snakes representing 10 species were recorded. Twenty-four Eastern Kingsnakes were documented, constituting nearly 20% of captures during the period. The intensive drift fence trapping protocol of the second study period spanned 19,380 trapping array days and, with supplemental opportunistic captures, yielded 2310 individuals representing 16 nonvenomous species. However, only one Eastern Kingsnake was documented during this period. This individual was captured at PH and represents < 0.05% of total nonvenomous individuals.

Despite a more intensive and systematic sampling effort, the 2002–2005 study documented a tremendous reduction in absolute and relative detection of the Eastern Kingsnake. We acknowledge that biases exist with all survey methods of snakes (e.g., Dodd and Franz 1995; Enge 2001; Gibbons and Semlitsch 1987; Greenberg et al. 1994; Kjoss and Litvaitis 2001; Prior et al. 2001). Different sampling protocols thus may have contributed to the observed decline in detection. However, the intensity of the 2002–2005 study, the ability of the sampling protocol to capture other large, semi-fossorial species such as the Corn Snake (*Elaphe guttata*) and Florida Pine Snake (*Pituophis melanoleucus mugitus*) (Stapleton 2005; Sash, unpubl. data), and the presence of many field personnel to potentially encounter Eastern Kingsnakes strongly suggest a real and remarkable population decline.

Research conducted at the Joseph W. Jones Ecological Research Center at Ichauway (JWJERC), located in Newton, Georgia, ca. 105 km (70 miles) north, stands in contrast to the Red Hills' Eastern Kingsnake decline. Like our study sites, JWJERC primarily consists of open canopied pine forests managed extensively with prescribed fire. Sampling at JWJERC employed a similar drift fence design using box traps which, despite a less intensive trapping regime, resulted in the capture of 60 Eastern Kingsnakes from 2003 to 2006 (L. Smith, pers. comm.). These data thus illustrate the ability of our drift fence design to capture Eastern Kingsnakes and, interestingly, point to the localized nature of the kingsnake decline. This localization is further demonstrated by surveillance cameras identifying Northern Bobwhite nest predators in the region. During an 8-year period beginning in 1999, nest monitoring cameras did not document Eastern Kingsnakes on TTRS or PH. Conversely, Eastern Kingsnakes were the most commonly documented snake species in the Albany, Georgia region (Staller et al. 2005) and predated 40% of all video-monitored nests during 2005–2006 (J. Carroll, W. Palmer, and D. Sisson, unpubl. data).

Although the Eastern Kingsnake was not documented on TTRS with either the drift fence trapping regime or nest-monitoring cameras, non-detection of a species does not indicate its true absence from the site (Kery 2002; Mackenzie 2005; Mackenzie et al. 2002). Therefore, we do not suggest that the Eastern Kingsnake has been completely extirpated from TTRS. In fact, a DOR specimen was noted in 2004 on a secondary road < 1.5 km from TTRS. However, our data strongly suggest a severe decrease in the Red Hills' Eastern Kingsnake population.

Causes for the kingsnake decline in the Red Hills are currently unknown. In the southeastern U.S., *L. getula* is found in a variety of habitats, often associated with low-lying wetland areas and overlapping much of the historical range of longleaf pine forests (Ernst and Ernst 2003; Gibbons and Semlitsch 1991; Krysko 2002; Means 2006; Means and Krysko 2001; Palmer and Braswell 1995). Our study sites appear to provide a landscape suitable for Eastern Kingsnakes; fingerlike drains and permanent and ephemeral wetlands are scattered across the open pine forest landscape and a large lake forms the southern boundary of TTRS. Additionally, the current landscape at our sites is generally similar to habitat in the 1970s. A thinning to reduce hardwood encroachment in the upland pine forests did occur at TTRS and PH during the late 1990s, but similar hardwood thinnings occurred at the Albany sites which documented Eastern Kingsnakes with surveillance cameras (W. Palmer, pers. obs.). Moreover, any land management activities that restore or maintain the open-canopy, pineland habitat with a vigorous herbaceous groundcover—the native habitat of the Eastern Kingsnake—should be beneficial to kingsnakes.

Our data provide further documentation of the statewide decline documented by Krysko and Smith (2005). The location of some of our study sites in southern Georgia additionally suggests that kingsnake declines may extend beyond Florida and into other portions of the southeastern United States. Current population statuses and the uncertainties surrounding the causes of kingsnake declines suggest a directive for future research (Krysko 2002; Krysko and Smith 2005). Studies should assess the status of the Southeast's populations and identify the underlying causes from which conservation solutions may be developed (Krysko 2002; Krysko and Smith 2005).

Acknowledgments.—We thank the staff of Tall Timbers Research Station, Inc. for their assistance with this project. Lora Smith and the Joseph W. Jones Ecological Research Center graciously shared Eastern Kingsnake capture records. Three anonymous reviewers provided useful comments to improve the manuscript. Funding was provided in part by grants from the United States Department of Agriculture – Wildlife Services and the National Geographic Society's Committee for Research and Exploration, the Warnell School of Forestry and Natural Resources, and Tall Timbers Research Station, Inc. Research during 2002–2005 was conducted under University of Georgia Institutional Animal Care and Use Committee

(IACUC) permits A2001-10100-c1 and c2.

While some behavioral aspects of Western Toads (*Bufo boreas*) have been documented (Campbell 1970; Carey 1978; Hailman 1984; Lilliwhite et al. 1973; Mullally 1958; Muths 2003; Muths and Corn 1997; Pimentel 1955), a great deal remains unknown. Toads are ectotherms that rely on environmental conditions to maintain body temperature and conserve water. Activity patterns appear to be critical in determining body temperature (Stevenson 1985), but the specific daily behaviors used by Western Toads for thermoregulation are not fully known. The greatest gap in our understanding of amphibians derives from how little is known about daily activity (Shoemaker 1992).

Conservation measures must incorporate aspects of amphibian ecology and behavior, such as habitat relationships and factors that affect their daily movements and other activities. The response of amphibian populations to landscape changes may range from negative (e.g., habitat fragmentation; Funk et al. 2004) to positive (e.g., fire; Hossack and Corn 2007). Thus, more detailed information on their daily behaviors may help us better anticipate the effects of landscape changes on amphibians.

We conducted a focal animal study with radiotelemetry to investigate and quantitatively characterize activity patterns, behavior, and microsite selection by Western Toads in southeastern Idaho. Whereas habitat selection has been studied in this area (Bartelt et al. 2004), we advance our understanding of this species' behavior

by focusing on how time of day/night, environmental conditions, and habitat relate to activity. Our results may be particularly relevant to the species' conservation in this region because the Western Toad has experienced population declines within the Greater Yellowstone Ecosystem (Koch and Peterson 1995).

Methods.—Our study was conducted within the Greater Yellowstone Ecosystem at Stamp Meadows in the Targhee National Forest (UTM 471117 E, 4928908 N; elevation approx. 2000 m) in southeastern Idaho, USA. Stamp Meadows was a seasonally flooded meadow that contained a 13 ha pond, bordered by willows (*Salix*) and aspen (*Populus*), and surrounded by coniferous forest habitats (*Pinus*, *Picea*, and *Abies*) that had been modified by logging.

We studied the daily activity of 4 male (nuptial pads present) Western Toads (range 60–85 mm snout–urostyle length; 40–70 g). We used a plastic belt to secure a 1.85 g BD-2GT transmitter (Holohil Systems, Ltd., Carp, Ontario, Canada) to each toad, a method that appears not to affect toad behavior (Bartelt and Peterson 2000; Murray and Fuller 2000).

We used focal animal sampling and observed one toad at a time with continuous recording of all instances of behavior and time (Martin and Bateson 1993). We made observations from 17 July to 3 August 1995 and divided each 24 h day into 8 observation periods of 3 h (periods: 1 = 0000–0259 h, 2 = 0300–0559 h, 3 = 0600–0859 h, 4 = 0900–1159 h, 5 = 1200–1459 h, 6 = 1500–1759 h, 7 = 1800–2059 h, and 8 = 2100–2359 h). Periods 1, 2, and 8 included times of darkness and are described as night while other periods are described as day. Periods 4, 5, and 6 are specifically described as midday. We randomly selected 2 periods each day and randomly selected a toad to observe during each of these periods. We observed each toad for each 3 h observation period.

We located toads with a Telonics TR-2 receiver and H-type directional antenna (Telonics, Inc., Mesa, Arizona). The observer sat approximately 3 m away from the toad under a camouflage net to minimize toad disturbance. We made night observations with a red-filtered 3.8 V incandescent light and used diffuse light peripheral to the central beam to reduce light intensity (Buchanan 1993). To test the effects of our light on the toads, we changed position relative to toads on several occasions during nighttime observations and the light did not appear to change direction of travel or orientation of toads.

We measured ambient (the area encompassing the study site as a whole) and microsite (the area within 3 m of the toad) weather conditions. Terrestrial ambient air temperature 1 m above ground and relative humidity were recorded with a CR10 data logger (Campbell Scientific, Inc., Logan, Utah) and PCRC-11 humidity transducer (Phys-Chem Scientific Corp., New York, New York) (<3% error between 12 to 100% RH, <1% error between 25 to 94% RH) placed near the center of the study site. Ambient measurements were taken every second, then averaged for each observation period. Terrestrial microsite air temperature was recorded 1 m above ground in shade with a Schultheis rapid registering mercury thermometer (Miller and Weber, Inc., New York, New York) at the onset, termination, and periodically during each observation period, then averaged for each observation period. Aquatic microsite water temperature, 1 cm below the water surface, also was recorded when toads were located in an aquatic microsite.

We recorded the sequence and time of all activity (e.g., attempt to capture prey using a tongue strike (feeding strike), distance traveled, position change, direction change, vocalization, habitat change, interaction with other toads) during observation periods. A minute was considered active if any detectable activity, other than breathing, was observed. Distance traveled, a subcategory and more conservative measure of activity, was used for data analysis. Distance traveled was measured in body lengths and distance in cm was estimated based on the known snout–urostyle length of each study animal. Microsite habitats (e.g., terrestrial, aquatic, underground) used by toads also were recorded. When toads were underground, ground level active minutes and distance traveled were recorded as zero because toads could not be observed directly and were not exposed to ground level environmental conditions.

Independent variables were time (observation period), average temperature (terrestrial ambient, terrestrial microsite, and aquatic microsite) during the observation period, and average relative humidity during the observation period. Temperature was categorized for analysis (< 5°C, 5–9.9°C, 10–14.9°C, 15–19.9°C, and >19.9°C). Dependent variables were active minutes and distance traveled. We used one–way analysis of variance (ANOVA) to test for potential differences between independent and dependent variables. To examine for potential differences between microsite temperature and ambient temperature, we conducted a regression analysis with indicator variables for observation periods. To examine for a potential association between relative humidity and distance traveled, we conducted a linear regression analysis. Statistical analyses were performed using Stata 8.0 software (StataCorp 2004, College Station, Texas).

Results.—We made a total of 32 observations of the four toads over the 8 observation periods (Table 1). Individual toads were seldom observed for the same number of minutes for each observation period. This was usually due to the toad disappearing from view. Toads were active during all observation periods with peaks in activity during the midday and night (Fig. 1). Activity differed among observation periods ($F_{7, 24} = 2.4$, $P = 0.05$).

During the day, toads were located at terrestrial retreat microsites, where they moved short distances and frequently changed orientation or position while basking in the sunlight. At these microsites, toads were seen making feeding strikes (Table 1) at crawling insects such as ants, spiders, and beetles. Only once did we see a toad strike at a flying ant. Toads were observed to feed during all observation periods except at night during period 1.

At night, the four toads traveled up to 40 m during period 8 from terrestrial microsites to aquatic microsites where other toads were also observed (Fig. 2). We also observed toads returning to terrestrial microsites in the early morning during periods 2 and 3. Relatively shorter distances of movement (0–0.95 m) occurred during midday observation periods 4, 5, and 6. Distance traveled differed among observation periods ($F_{7, 24} = 3$, $P = 0.02$).

In addition to a relationship between distance traveled and observation period, distance traveled was significantly different among microsite temperature categories ($F_{4, 27} = 2.9$, $P = 0.04$). Toads traveled furthest when microsite air temperature was 5–9.9°C or 10–14.9°C, and traveled shorter distances when temperature exceeded 15.0°C (Fig. 3). Observation period and temperature are related and the relationship represents a sinusoidal pattern

TABLE 1. Observation periods and activities of four Western Toads radiotracked in southeastern Idaho, USA, in July and August 1995.

(Fig. 4). Ideally, a multivariate analysis would be performed to evaluate the relative contributions of observation period and temperature to distance traveled, but the small sample size of this study prevents such analysis. However, distance traveled appears to be related more to observation period than temperature. For example, the average microsite temperatures during observation period 8 were category 2 (5–9.9°C) and 3 (10–14.9°C); and the average distance traveled during this period was 24.4 m. However, when the same average microsite temperature categories 2 and 3 occurred during other observation periods, the average distance traveled was only 7.9 m. This suggests that the longer distances traveled during observation period 8 were related in part to time of day rather than simply microsite temperature. Relative humidity also appears to contribute to distance traveled. For example, ambient relative humidity was significantly greater when toads traveled 9 m (88.3 ± 2.5% vs. 78.3 ± 2.4%; $t = 1.73$; P = 0.047).

Microsite temperature appears to be related to microsite habitat selection. Microsite air temperatures tended to be warmer than the surrounding terrestrial ambient air temperatures during periods 3, 4, 5, and 6 (Fig. 4) and were significantly warmer during midday periods 4 and 5 ($F_{1, 14} = 7.6$, P = 0.02 and $F_{1, 16} = 10.6$, P = 0.005, respectively). This suggests toads selected midday microsite habitat based at least in part on temperature. At night, ambient and microsite air temperatures were often near freezing. In these cold conditions, toads were found in warmer habitats, such as aquatic microsites. When toads were in aquatic microsites, water temperatures were up to 3°C warmer than terrestrial ambient air temperatures and 13°C warmer than terrestrial microsite air temperatures. In the later dates of the study, two toads traveled greater than 80 m from aquatic microsites and did not return to aquatic microsites at night. These two toads were located underground in a rodent hole and under a tree stump during cold nights. While driving to and from the study site at night on these cold nights, we also observed several toads in crouched positions on exposed dirt roads.

Vocalization was recorded on separate occasions for each toad, including occasions not provoked by contact with another animal. A toad was heard vocalizing while: 1) an ant was crawling on its head; 2) turning body orientation; 3) in an underground hole; and 4) in the process of digging in plant material. On two occasions at night, a toad vocalized when another toad attempted to amplex with it; upon vocalization, the other toad released its grasp and moved toward and clasped another nearby toad. On two other occasions at night, we heard three male toads, positioned at separate and distant (e.g., 50–70 m) points in the pond, repeatedly and sequentially vocalize.

Discussion.—We observed four male Western Toads during midsummer at high elevation in southeastern Idaho. We found them to be active during all observation periods with a peak in activity

in the midday and early night. Despite being active in the midday, distance traveled was limited during midday. Distance traveled was furthest in the early night when toads traveled to warmer aquatic microsites. Our results are similar to Mullally (1958) who described the activity patterns of Western Toads, especially in the higher elevations, as primarily nocturnal with some diurnal activity. However, like other amphibians, activity patterns of Western Toads are not adequately described simply as diurnal, nocturnal, or crepuscular (Hailman 1984). Data from our study show behavior patterns and how variation in environmental conditions may affect toad biology.

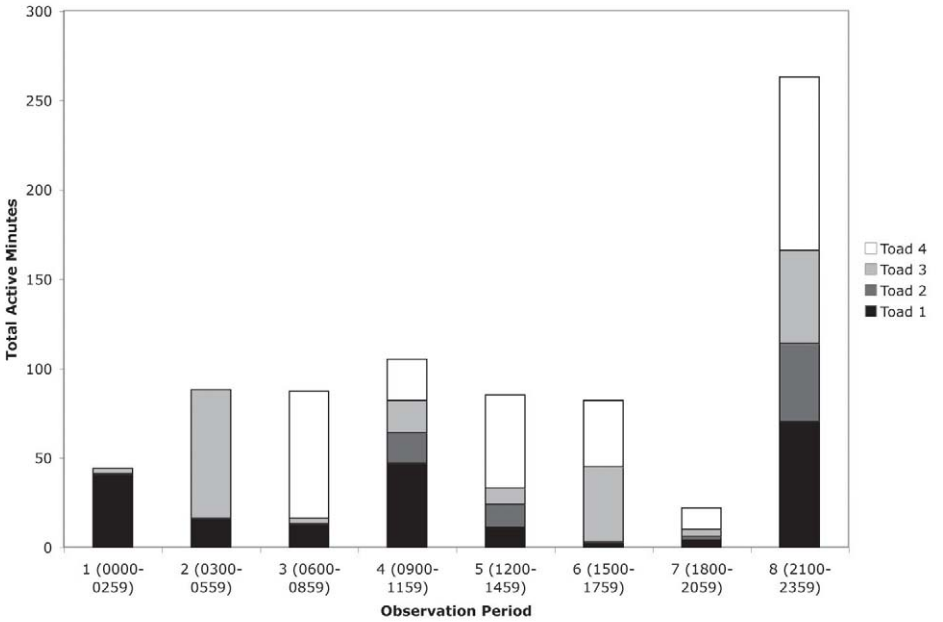

FIG. 1. Western Toad activity patterns were associated with observation period in southeastern Idaho, USA (ANOVA, P = 0.05).

We observed behavior patterns we believe were used to regulate body temperatures and water balance. The regulation of body temperature is primarily behavioral (Spotila et al. 1992) and the choices of times for daily activity appear to be the most critical behavior in determining body temperature (Stevenson 1985). During the day, each toad was located while basking in sunlight at a terrestrial retreat site. These microsites may have been selected, in part, due to their warmer temperatures relative to the surrounding habitat. Our observations that air temperatures of terrestrial retreat microsites were warmer than surrounding ambient air temperatures supports those of Campbell (1970), that toads basked in sunlight as a method to increase body temperature.

Distance traveled was furthest at night, consistent with the observations of other studies. Western Toads emerge and become active (including travel) at night (Mullally 1958; Pimentel 1955), during the hours of our observation period 8, 2100–2359 h (Hailman 1984). The toads may reduce water loss by traveling at these times when temperatures did not exceed 14.9°C and relative humidity generally did not drop below 78%. In addition, when < 80 m from an aquatic microsite, all four toads in our study were found to travel to an aquatic microsite at night. We suggest two reasons for the presence of toads in an aquatic microsite at night. First, during cold nights, the microsite water temperature was warmer than both ambient and terrestrial microsite air temperatures. Water is more thermally stable than many of the terrestrial microhabitats available to toads (Lillywhite 1970). The toads were, therefore, likely able to maintain a warmer body temperature by entering the aquatic microsite because an amphibian in water rarely experiences a body temperature more than 2°C different than the water (Spotila et al. 1992). Second, by entering the aquatic microsite, toads likely were able to regain, by absorption, any water lost during midday sun basking. Many amphibians move between aquatic and terrestrial microsites (Shoemaker 1992). *Bufo punctatus*, for example, has been described to have a pattern of behavior similar to the Western Toads we observed with up to 85 m of travel from its burrow to a small stream at night and returning to the same burrow early in the morning (McClanahan et al. 1994). Mullally (1956) also described Western Toads traveling to aquatic microsites

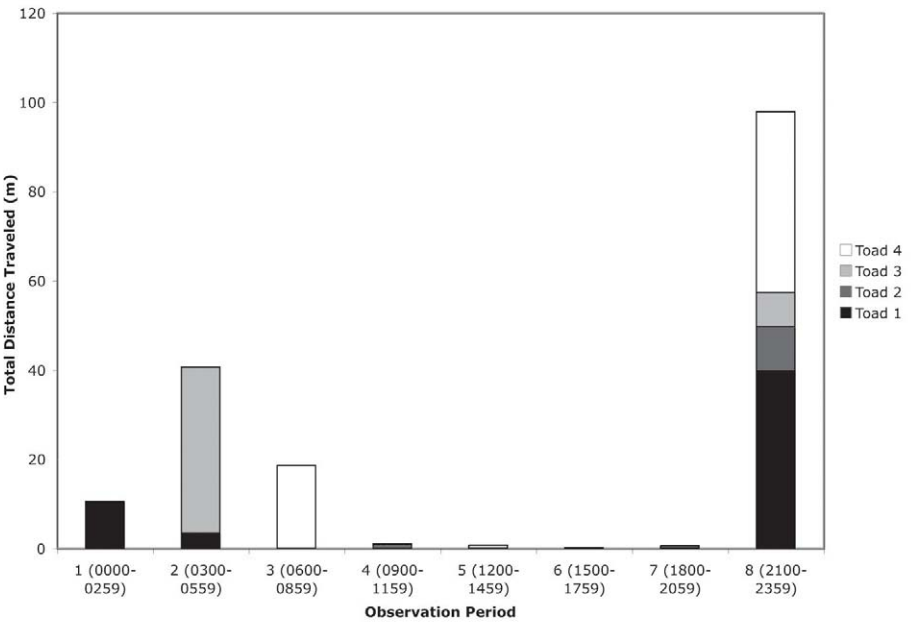

FIG. 2. Distance traveled by Western Toads was associated with observation period in southeastern Idaho, USA (ANOVA, P = 0.02).

in times of dry weather, probably to rehydrate.

Bartelt et al. (2004) observed Western Toads traveling 1.3 km from breeding sites in the late summer and these toads did not return to water. In the later dates of our study, two toads traveled from and were not found to return to aquatic microsites. These toads were located underground in a rodent hole and tree stump where they had no surface level activity. Limits on activity have been shown to be an important factor in water balance (Tracy 1976). Under moderate conditions of temperature and relative humidity, most amphibians cannot survive for more than a day in circulating air, because they quickly dehydrate (McClanahan et al. 1994). Retreating to cover likely reduces both evaporative water loss from midday basking and rehydration needs. Therefore, Western Toads without access to an aquatic microsite likely retreat from exposed sites during times of dryness, as we observed.

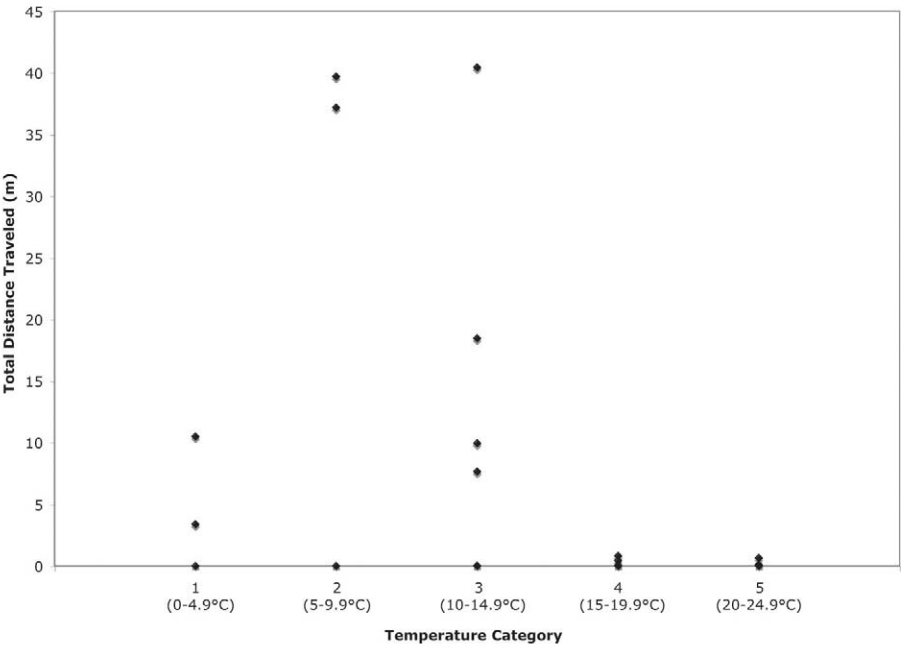

FIG. 3. Distance traveled by Western Toads was associated with microsite temperature category in southeastern Idaho, USA (ANOVA, P = 0.04).

In addition, we often found several non–telemetered toads on dry dirt roads at night. Mullally (1958) also found Western Toads on the road and Hailman (1984) discussed toads specifically seeking the road at night. The toads we found on roads were often in a crouched position, which maximized surface contact. Roads are not covered by vegetation and are exposed to radiant energy from the sun, which is stored and lost at the dirt surface. Typical of any system with storage and resistance, there is a time lag in heat flux out of dry soil (Campbell and Norman1998). The toads may crouch on the dry soil road to increase body temperature from this release of heat. Campbell (1970) and Carey (1978) proposed that toads increase temperature by conduction of heat from substrate. For toads on the road, mortality by vehicles may be a significant cause of death. We have previously reported the death by vehicle of a telemetered toad (Bartelt and Peterson 2000).

Mullally (1956) reports that male Western Toads vocalize only when provoked through contact with other animals such as when other males amplex them. In this situation, the clasped male vocalizes, whereupon the clasping male releases its hold. This interaction was observed and the presence of a radio-transmitter did not appear to inhibit or discourage other toads from clasping telemetered toads. We also found that toads vocalize at times when there is no contact by other animals, particularly at night when distant toads repeatedly called in sequence. The fact that vocalization was heard at times other than contact with other animals is interesting and may indicate that vocalization plays a larger role than that of communicating a release during amplexus or provocation.

The observations in our study represent a behavior sample of adult male free-living Western Toads. The activity and habitat use at different times and temperatures likely reflect thermal and water regulatory behavioral strategies. Though limited in sample size, our results demonstrate nocturnal peaks in travel with some level of activity present throughout the 24 h day, including a moderate diurnal component. Toads traveled over a narrow range of tem-

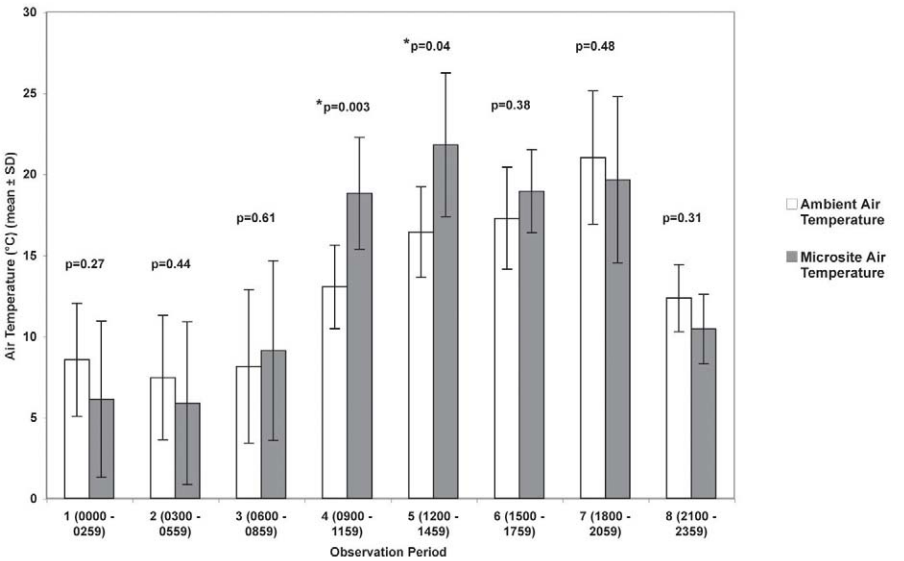

FIG. 4. Average microsite air temperature (°C at 1 m) where a Western Toad was located compared to ambient air temperature (°C at 1 m) during each observation period in southeastern Idaho, USA. Microsite air temperatures of the retreat sites selected by toads during periods 4 and 5 were warmer than ambient air temperatures.

peratures, and traveled longer distances during periods of high humidity. Toads were often found in aquatic microsites and on roads at night and at terrestrial retreat sites during the day.

Acknowledgments.—This research was supported by grants from the USDA Forest Service Intermountain Research Station, the Targhee National Forest, the National Fish and Wildlife Foundation, Theodore Roosevelt Memorial Fund of the American Museum of Natural History, and the Graduate School and Department of Biological Sciences of Idaho State University. The Idaho State University Animal Welfare Committee approved this study (protocols: 12-92-89 and 3-93-106) and state and federal permits were obtained to access the study site and conduct research. We thank John S. Addis, D. Grant Hokit, Kay A. Satre, and Jean Smith for reviewing previous versions of this manuscript.

New Guinea, the world's largest and highest tropical island, has been identified as one of the world's five High Biodiversity Wilderness Areas (Mittermeier et al. 2003). The island occupies less than 0.6% of global land area but harbors 5–7% of the world's biodiversity (Beehler 1993; Dinerstein and Wikramanayake 1993; Myers et al. 2000). The herpetofauna of New Guinea currently accounts for approximately 5% of the world's reptile and amphibian diversity (Allison et al. 1998). Remarkably, this is an underestimate of true diversity as species accumulation curves for both lizards and frogs continue to increase dramatically without hint of plateau (Fig. 1). The tallest peak on the island exceeds 5000 m and the rugged topography encompasses a wide range of habitat

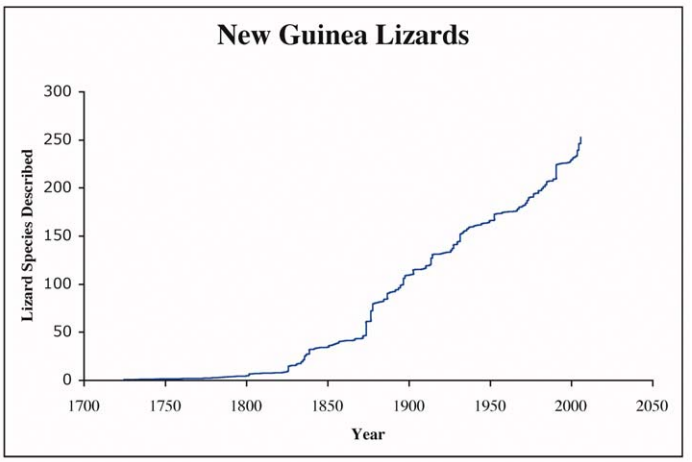

FIG. 1. Species accumulation curves for New Guinea frogs and lizards.

types packed into an area one-tenth the size of the United States. These habitats include mangrove forests, lowland eucalypt savannas, dense lowland rainforests, sago palm swamps, montane moss forests, cloud forests, alpine grasslands, and tropical glaciers on the tallest peaks. The New Guinea herpetofauna can be found in all but the last of these habitats.

Over the last several decades extensive logging has severely impacted the expansive lowland rainforest on the north coast of Papua New Guinea (Beehler 1993). Here we report on a 15-day survey of terrestrial amphibians and reptiles from the area surrounding Utai Village (3°23.765'S, 141°34.974'E, 208 m elev.) in north-central New Guinea in Sandaun Province, Papua New Guinea. Utai Village is situated on the Gedik River, a northern tributary of the Sepik River. The Sepik is the longest river on the island and possibly the largest uncontaminated drainage system in Australasia with a catchment of approximately 80,000 km^2 (Allen and Coates 1990). Utai Village is located at the intersection of upland and forest flood plains. North of Utai the rolling hills give rise to foothills of the Bewani Mountains and to the south is vast expanse of nipa flood plain forest that extends to the Sepik River. The forest includes primary, successional, and riparian lowland broadleaf evergreen forest as well as extensive Sago Palm (*Metroxylon sagu*) swamps. The immediate areas surrounding Utai village have been used for traditional shifting fruit and vegetable gardens and extensive harvesting of Sago Palms for food. The larger surrounding areas are largely unspoiled lowland rainforest in the extensive and broadly contiguous Northern New Guinea lowland ecoregion that contains diverse habitats including lowland and hill forest, grassy swamps, swamp forests, savannas, peat swamp forests, and woodlands (Conn 1995; Gressitt 1982; Henty 1981; Womersley 1978). Although the forests around Utai have

TABLE 1. Checklist of the terrestrial amphibian and reptile fauna of Utai northwestern Papua New Guinea. We refer to a species as 'Common' if it is typically encountered in an approximate 8-person-hour search period. Species listed as 'Uncommon' are encountered infrequently in the area around Utai and typically require more than a single day/night search of 8-person-hours to locate. References refer to general literature associated with each species.

[2]Reported by Kraus and Allison 2006.

yet to be commercially logged, logging roads are encroaching rapidly from the north and will reach the village within the next several years.

To date there have been no comprehensive herpetofaunal reports from northwestern Papua New Guinea. Here we compile a list of terrestrial reptile and amphibian species from the vicinity of Utai based on a field survey conducted from 27 June to 12 July 2006 (Table 1) as well as from previous fieldwork (CD) and published reports (Kraus and Allison 2006). Kraus and Allison (2006) reported range extensions for reptiles and amphibians along the northern versant of Papua New Guinea that included three species not collected by our team but reported within 5 km of Utai village. The fauna, exclusive of crocodilians and turtles, includes 79 species comprising 16 snakes, 30 lizards, and 33 frogs representing 40 genera in 11 families (Table 1). This list undoubtedly is an underestimate of the true diversity present in the region. Specific specimen (and associated tissues) and locality information can be accessed via a searchable database of the LSU Museum of Natural Science reptile and amphibian collection (http://www.lsu.edu/museum).

SPECIES RICHNESS, TAXONOMY AND SPECIES-COMPLEX GROUPS

There are a large number of species complexes in the diverse New Guinea herpetofauna, especially among the scincid lizards and microhylid frogs (e.g., Austin 2006). In addition to obvious species complexes, many currently recognized species likely harbor cryptic species (Bickford et al. 2006). Species richness, therefore, is likely much greater than is presently documented from our survey. We are taking a multidisciplinary approach using morphological and molecular data to tease apart many of the species complexes as well as to describe the species obviously new to science. Below we comment on and address some of the taxonomic impediments to understanding the terrestrial amphibian and reptile fauna in the Utai area.

Treesnakes of the genus *Dendrelaphis* are easy to identify to the generic level but extensive geographic variation in color pattern and scalation, inadequate keys, and cryptic diversity make *Dendrelaphis* a problematic group (McDowell 1974; O'Shea 1996). We collected one species that keys out to *Dendrelaphis punctulatus* but has a drastically different color pattern and thus

may represent an undescribed species. In addition, we collected several specimens of what is clearly an undescribed species of *Dendrelaphis*. Keelback snakes of the genus *Tropidonophis* have had a taxonomically complicated history, having been assigned to such diverse genera as *Amphiesma*, *Macropophis*, *Natrix*, and *Styporhynchus* (Malnate and Underwood 1988; O'Shea 1996). *Tropidonophis* are easily distinguished from other New Guinean snakes by having prominently keeled dorsal scales, but species identification remains difficult. We collected three specimens of the elapid genus *Aspidomorphus*. One adult and juvenile were easily assigned to *A. muelleri* and a third specimen was not readily assignable to any of the three currently recognized species of *Aspidomorphus* and likely represents a species new to science.

The angle head lizards of the agamid genus *Hypsilurus* have been recently revised (Manthey and Denzer, 2006). Manthey and Denzer (2006) recognize 14 species of *Hypsilurus*, while acknowledging that this diversity is undoubtedly an underestimate. There are two species of *Hypsilurus* in the Utai region. *Hypsilurus modestus* is a small-bodied (maximum SVL = 107 mm) *Hypsilurus* with a broad distribution throughout the Papuan region (New Guinea and nearby associated islands) and is common in the Utai area. A second *Hypsilurus* species does not key to any of the currently described species and likely represents a species new to science.

The gecko fauna of New Guinea consists of seven genera: *Cyrtodactylus*, *Gehyra*, *Gekko*, *Hemidactylus*, *Hemiphyllodactylus*, *Lepidodactylus*, and *Nactus*. Six of these seven gecko genera were found in the Utai region with the seventh, *Hemiphyllodactylus*, representing an uncommon, hard to find and/or patchily distributed gecko poorly represented in collections; one of us (CCA) has collected just three individuals of *Hemiphyllodactylus* in 18 years of fieldwork on the island. Although *Hemiphyllodactylus* was not recorded from the Utai area it may occur in the region. *Cyrtodactylus*, *Gehyra*, and *Nactus* represent taxonomically challenging groups in need of revision and study. The geographic distribution and specific-level delineation for virtually all species of New Guinea geckos is not well understood and many collections have misidentified taxa. Currently ten species of *Cyrtodactylus* are described from New Guinea, but several undescribed species exist in collections (Kraus and Allison 2006). *Cyrtodactylus sermowaiensis* was collected regularly at night and was the most abundant species of *Cyrtodactylus* present. Two specimens of a much larger species of *Cyrtodactylus* where collected. These are similar to *C. novaeguineae*, but differ in several aspects of morphology and likely represent an undescribed species.

The diverse skink fauna of New Guinea includes many species complexes (Austin 2006). Preliminary molecular investigations have revealed significant population structure within most widespread species, indicating a greater level of species-level diversity than currently recognized.

The frog fauna of New Guinea is incredibly diverse with more than 350 described species (Amphibian Species of the World Database http://research.amnh.org/herpetology/amphibia/index.php) with 90% endemism (Mittermeier et al. 2003). The rate at which new species are being described is extremely rapid and there is no sign of an asymptote (Fig. 1). Frog diversity in the region is expected to exceed 600 species (Günther 2006). Microhylid frogs are the most diverse group in New Guinea. Our survey included sound recordings of male frogs in order to identify and describe new taxa. Preliminary analyses suggest multiple species new to science in the microhylid genera *Hylophorbus*, *Oreophryne*, and *Xenobatrachus* (Table 1). In addition to the diverse microhylids, the hylid genus *Litoria* is also species rich with a new *Litoria* recently described from Utai (Richards et al. 2006) and another likely undescribed species recorded on our survey.

Notably absent from the Utai region were the common and widespread introduced toad *Bufo marinus* and the skink genus *Carlia*. The latter has a broad range across New Guinea and its members are typically some of the most abundant diurnal lizards in village, garden, and forest edge habitats. *Bufo* and *Carlia* were, however, common in the Provincial capital of Vanimo 75 km NW of Utai on the coast.

Although our survey targeted terrestrial herpetofauna we did collect one specimen of a juvenile *Elseya novaeguineae* (McDowell 1983). In addition, the New Guinea freshwater crocodile (*Crocodylus novaeguineae*) were reported by locals to be in the general vicinity but had been primarily extirpated from the nearby area. Freshwater crocodiles are distributed in lowland to upland areas throughout the island of New Guinea (Hall 1989).

Regional checklists for New Guinean herpetofauna are extremely limited. The only other checklists for the north coast are both from the Kau Wildlife Area (Austin 2006; Read 1998). These limited data allow partial comparative measurements of species richness across a spatial scale of approximately 500 km (Fig. 2). Alpha diversity refers to the total diversity for a given site or region; alpha diversity is 79 at Utai and 67 at Kau. Gamma diversity is the total summed diversity across all sites and the gamma diversity for Utai and Kau is 104. Beta diversity refers to the change in species richness between different sites and is a summed measure of those species unique to two or more compared areas, thus beta diversity reflects the non-overlap of species diversity. The beta diversity between Utai and Kau is 62, meaning that there are 62 species that are found either solely in Utai or Kau (conversely, there are 42 species in common between the two sites). These data suggest that alpha diversity is similar across these two sites and that beta diversity is quite high.

Acknowledgments.—We thank the people of Utai Village for the privilege to conduct fieldwork on their land. In particular we thank P. Tano and Jebed for their hospitality and support. We also thank B. Roy, V. Kula, and B. Wilmot from the PNG Department of Environment and Conservation, and J. Robins from the PNG National Research Institute who provided assistance with research visas and export permits. The Sandaun Provincial Government kindly granted approval for our research in the Province. Partial support for fieldwork by CD at Utai was provided by Conservation International. Steve Richards (South Australian Museum) assisted with frog identifications and provided valuable comments. This manuscript was improved from comments by David Bickford and two anonymous reviewers. All research was carried out under LSU IACUC protocol 06-071. This research was funded in part by National Science Foundation grants DEB 0445213 to CCA.

A species' mating system is an important life history characteristic that impacts many aspects of its ecology and evolution. Animal mating systems are differentiated by the number of mates each gender has in a breeding season. Many temperate pond-breeding anurans display what is likely a polygynandrous mating system, which may vary with the operational sex ratio of a population (Halliday and Tejedo 1995; Lode et al. 2004). There is genetic evidence for multiple paternity in some anuran amphibians, where eggs from a single mass are fertilized by more than one male (D'Orgeix and Turner 1995; Laurila and Seppa 1998; Lode and Lesbarreres 2004; Roberts et al. 1999; Sztatecsny et al. 2006). However, the ability of males to fertilize eggs from more than one female during a breeding season has not been demonstrated using genetic techniques. In the course of a larger study, we had the opportunity to look for this phenomenon in a population of Northern Leopard Frogs (*Rana pipiens*).

What is known about the mating system of *R. pipiens* suggests that males may be capable of breeding with multiple females in a single season. *Rana pipiens* is an explosive breeder, and the breeding season can last from a few days to a few weeks (Gilbert et al. 1994 and references therein). If female synchrony is high, there is a limited time when males can fertilize eggs, which could result in a functionally monogamous mating system where only full-sibs and unrelated individuals will be present among the progeny produced in a given year. However, as is true for other anuran species, males sometimes remain at breeding sites after being observed in amplexus (C. A. Paszkowski, unpubl. data), which suggests they may be attempting to find additional mating partners. Males can increase their fitness by producing offspring with more than one female in a breeding season (Arnold and Duvall 1994; Clutton-Brock and Vincent 1991). If males are successful in fertilizing eggs from more than one female, then half-sibs will also

be found within a cohort. In laboratory studies, male *R. pipiens* have been observed breeding with more than one female during a reproductive bout, although a decline in fertilization rates may have resulted (Paula Jackman, Environment Canada, pers. comm.).

Rana pipiens is considered a Species of Special Concern by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC 2000) as its numbers have been declining, especially in the western part of its range (Rorabaugh 2005). During a study on the conservation genetics of 14 populations of *R. pipiens* from across central and western Canada, we found that the distribution of genotypes from 31 tadpoles sampled from Belza Pond, Grasslands National Park, Saskatchewan, deviated significantly from linkage equilibrium at 10 of 28 pairwise locus comparisons (see *Results*). This was unusual, as no locus pairs deviated from linkage equilibrium when all populations were considered as a whole (data not shown). In this larger scale study, "populations" were defined as either individuals from a single pond or genetically similar nearby ponds. Deviation from linkage equilibrium can occur if related individuals are present in a sample. *Rana pipiens* lays up to 7000 eggs per breeding season (Corn and Livo 1989), so it is possible that multiple larvae sampled from a pond may be from the same egg mass. Because the Belza population was the only one from which tadpoles were sampled (as opposed to terrestrial juveniles and adults) we predicted that the distinct pattern observed at Belza was a result of sampling some combination of full-sibs (tadpoles likely originating from the same egg mass sharing both parents), maternal half-sibs (tadpoles likely originating from the same egg mass sharing a mother but not a father), and paternal half-sibs (tadpoles likely originating from different egg masses sharing a father but not a mother). To test this we estimated the genetic relationships among the tadpoles from Belza to determine if the sampled individuals shared a familial relationship. If paternal half-sibs are present in the population, this would be the first genetic confirmation that multiple fertilizations with different females in a single breeding season are possible by male *R. pipiens*, and increases our knowledge of the mating system in this species.

Materials and Methods.—Grasslands National Park, Saskatchewan, is located within the mixed-grass prairie ecosystem of North America. Belza Pond is ca. 20 × 20 m, located at 49°09'128"N, 107°31'546"W within Grasslands National Park. It is 500 m from the Frenchman River, but areas between ponds are quite dry and movement of frogs among ponds is likely infrequent and highly dependent upon rare weather patterns that cause high rainfalls. As Belza Pond is spring-fed and in a valley, it generally holds water throughout the year, despite having a maximum depth of 150 cm. The average precipitation at the Val Marie, Saskatchewan, weather station (approximately 10 km from Belza Pond) over a 12-month period from July to the following June from 1990 to 2004 was calculated as 410.19 mm (s.d. 104.47 mm, National Climate Data and Information Archive, Environment Canada 2007; years with missing data were not included in the analysis). Annual precipitation for 2003–2004 was 397.1 mm. Tailclips were collected from 31 tadpoles of *R. pipiens* at Belza Pond on a single date (19 July 2004). Tadpoles were collected opportunistically, but explicit effort was made to sample animals from throughout the pond. Little is known about the Belza population of *R. pipiens*, but at the time of sampling no adults and approximately 100 young of year were observed. Tadpoles were at a minimum of Gosner Stage 42 (where forelimbs erupt, Gosner 1960), and therefore capable of having moved throughout the pond since hatching.

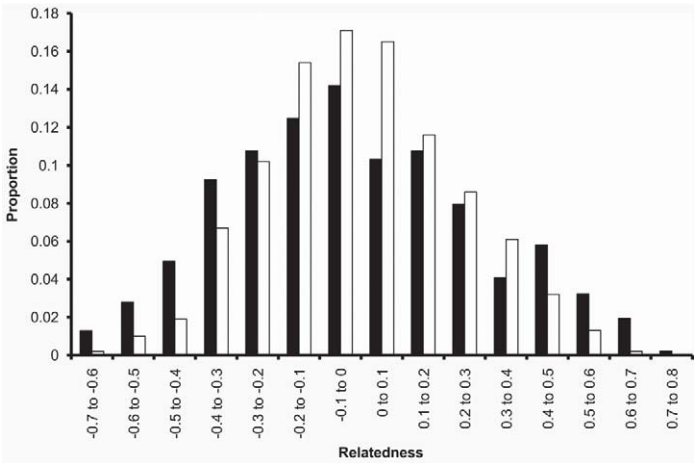

FIG. 1. Frequency histograms of Queller and Goodnight's (1989) relatedness values for the 31 Belza tadpoles (black) and 1000 simulated unrelated individuals (white). Some of the relatedness values are higher in the Belza population than in individuals that are simulated to be unrelated, suggesting the presence of related individuals in our sample.

DNA was extracted using a DNeasy Tissue Kit (Qiagen). For microsatellite analysis, we used loci Rpi100, Rpi101, Rpi103, Rpi104, Rpi107, Rpi108 (Hoffman et al. 2003), Rp193, and Rp415 (Hoffman and Blouin 2004a). Each PCR amplification contained 120 μM dNTPs, 0.27 μM each primer (one of which was dye-labeled), 1.5 U Taq polymerase, 1X PCR buffer (10 mM Tris buffer, pH 8.8, 0.1% Triton X-100, 0.16 mg/mL bovine serum albumin, 50 mM KCl), and ~40 ng genomic DNA in a final volume of 15μL. Rpi101 and Rpi193 were amplified with 2.0 mM $MgCl_2$, while all other PCR reactions contained 2.5 mM $MgCl_2$. PCR cycling conditions were as follows: 1 min at 94°C; 3 cycles of 30 s at 94°C, 20 s at 44°C, 5 s at 72°C; 30 cycles of 15 s at 94°C, 20 s at 45°C, 1 s at 72°C; 30 min extension at 72°C. PCRs were performed on an Eppendorf Mastercycler and electrophoresed on a 3100-Avant Genetic Analyzer (ABI).

All loci were examined for deviations from Hardy-Weinberg equilibrium and linkage disequilibrium using GENEPOP 3.4 (Raymond and Rousset 1995). Queller and Goodnight's (1989) relatedness was calculated with KINSHIP 1.3.1 (Goodnight and Queller 1999). Genotypes for 1000 pairs of unrelated individuals were also simulated with this program by choosing alleles at each locus based on the allele frequencies in the Belza population sample. The relatedness values from simulated unrelated individuals can be compared to those observed in the Belza population to determine if the Belza individuals had higher relatedness values (and were thus more closely related) than would be expected by chance. Individuals were assigned to full-sib families nested within half-sib groups using COLONY 12 (Wang 2004). This program is known to be effective at identifying full- and half-sib groups in a number of species (e.g., Carlsson et al. 2007; A. J. Wilson et al. 2005). The COLONY program utilizes maximum likelihood and allows for errors through allelic dropout and mistyping. Both types of error rates were set to 0, 0.01 and 0.02, and runs were per-

formed at each of these settings with 10 initial random seeds.

All individuals but one were sequenced for an 812 base pair (bp) fragment of mitochondrial DNA, corresponding to bases 27-838 of the NADH dehydrogenase subunit 1 (ND1) gene. The region was amplified using newly designed primers, RpND1F (5' GGT TCA AAT CCC CTT ACT A 3') and RpND1R (5' AGT TGG TCA TAG CGG AAT CGT G 3'), in a 25 μl reaction containing 1X PCR buffer, 2.5 mM $MgCl_2$, 160 μM dNTPs, 0.4 μM each primer, 1 U Taq polymerase, and ~50 ng genomic DNA. Cycling conditions were: 5 min at 95°C; 35 cycles of 1 min at 94°C, 1 min at 54°C, 90 s at 72°C; 5 min extension at 72°C. PCR products were purified using the QIAquick PCR purification kit (Qiagen) and directly sequenced using the forward primer and the BigDye v.3.1.1 (Applied Biosystems) chemistry following the manufacturer's protocol. Individuals with variable sites near the priming region were also sequenced using a reverse primer RpND1R.int (5' TTG AGG ATA CCG AGG CAG AGC 3') for sequence confirmation. Unincorporated dye terminators were removed using the DyeEx 96 kit (Qiagen) and the fragments were resolved using an Applied Biosystems 3730 capillary sequencer. Sequences were analyzed, basecalled, and aligned with ABI Prism SeqScape software v.2.1 (Applied Biosystems).

Results.—The number of alleles in the Belza Pond population per microsatellite locus ranged from 2 to 10, with a mean of 5.25. The Belza population was significantly out of Hardy-Weinberg equilibrium when the exact Hardy-Weinberg test was used (Haldane 1954) and all loci were considered (χ^2_{16} = 31.16, P < 0.05). We also observed significant (P < 0.05) linkage disequilibria for 10 of 28 locus comparisons. Two of these tests remained significant following Bonferroni correction for multiple tests (P < 0.0018). Neither linkage nor Hardy-Weinberg disequilibrium was observed in the 13 other populations of *R. pipiens* we examined from across western and central Canada (data not shown). The distribution of pairwise relatedness values for the Belza population and unrelated individuals simulated from this population's allele frequencies are shown in Fig. 1. On average, unrelated individuals have a relatedness value of 0. This increases to 0.25 for individuals related at the half-sib level, and 0.5 for full-sibs. Twenty-five of the 465 observed pairwise comparisons within the Belza population (5.4%) had relatedness values at the full-sib level or higher. Four of these comparisons (0.9%) were higher than any of the 1000 simulated r-values for unrelated individuals, and 28 (6.0%) were outside of the upper bound of the 95% confidence interval of the distribution of simulated unrelated individuals (-0.425, 0.473), suggesting a high degree of relatedness in these samples. The shapes of these distributions were significantly different from one another (G-test for heterogeneity based on counts grouped by 0.1; d.f. = 14; P < 0.0005).

Relatives were common in our sample, as only two individuals from the Belza population did not assign to a nested half-sib group generated by COLONY (full-sib groups 8 and 9 in Fig. 2). The most common arrangement of full-sib groups within half-sib groups (after examining all error rates and initial seeds) and the mitochondrial haplotypes possessed by these individuals is shown in Fig. 2. Other arrangements were similar, and saw either full-sib group 4 merged with full-sib group 3 or full-sib group 2 merged with full-sib group 1. Half-sib group B was the largest, containing 4 full-sib groups and 22 individuals (71% of the sampled population). Full-sib group membership ranged from 1 (groups 1, 2, 8, and 9) to 10 (32% of the sampled population, group 5). Two different mtDNA haplotypes were observed in the Belza population, differing by three synonymous mutations. These mutations all occurred in the first 580 bp of our sequenced region which overlapped the region sequenced by Hoffman and Blouin (2004b), and thus their haplotype numbering system was used. One of the nested half-sib groups (group B) possessed both of the haplotypes observed at Belza. Individuals in full-sib groups 3 and 4 shared haplotype 1 (GenBank accession AF548568) and all other individuals shared haplotype 7 (GenBank AF548575). The individual for which mtDNA sequence was unavailable was assigned to full-sib group 5.

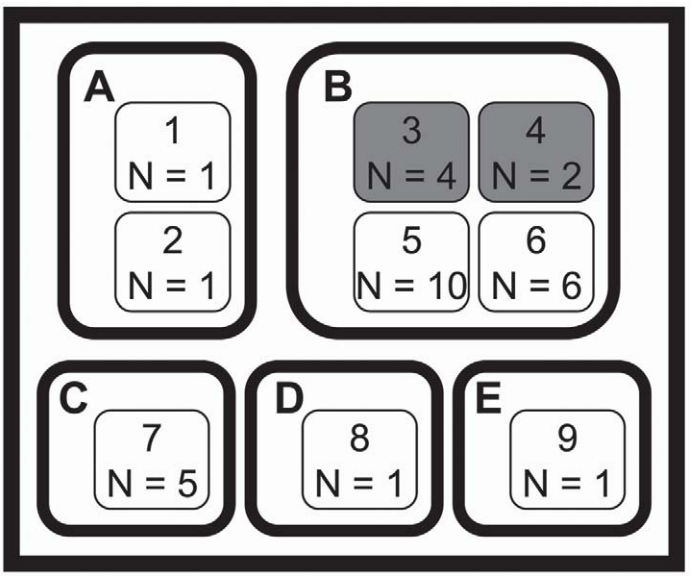

FIG. 2. Partitioned full-sib groups (1–9) nested within half-sib groups (A–E) and the sample size for each full-sib group based on microsatellite data. The largest square represents the sample from Belza Pond, Saskatchewan. Gray full-sib squares possess mitochondrial haplotype 1 and white squares possess haplotype 7.

Discussion.—Sampling tadpoles from the same age cohort allowed us to examine parentage in a population of *R. pipiens* using genetic techniques. Our results show that sib-groups may be commonly encountered among tadpoles. When a sample of individuals from a population consists of related individuals, the genetic material they share is overrepresented. For example, if a pair of full-sibs sharing 50% of their genetic material is sampled, then the shared material will occur in the sample not once, but twice. As populations in both Hardy-Weinberg and linkage equilibrium are assumed to consist of unrelated individuals, the presence of genetic material shared between relatives violates this assumption resulting in the rejection of these hypotheses. Under the assumption that the entire population is randomly mating, larvae analyzed from Belza did not represent a random sampling of the genetic diversity in this population, as suggested by the rejection of the null hypotheses of Hardy-Weinberg and linkage equilibria. This is likely due to the presence of related individuals within our sample, which is also supported by the fact that some pairwise relatedness values in the Belza population are elevated over what would be expected in an unrelated sample of individuals (Fig. 1).

The presence of related tadpoles in our Belza sample allowed us to test if male *R. pipiens* are capable of reproducing successfully with more than one female per breeding season. Sibship analysis identified high membership in full- and half-sib groups. These patterns could be explained by multiple paternity (a female breeding with multiple males) which is known to occur in anurans (D'Orgeix and Turner 1995; Laurila and Seppa 1998; Lode and Lesbarreres 2004; Roberts et al. 1999; Sztatecsny et al. 2006), or multiple fertilizations by males, which has not been documented. Within half-sib group B (Fig. 2), two full-sib groups possess haplotype 1 while the other two full-sib groups possess haplotype 7. The only way this pattern can occur is if a single male bred with at least two females that possessed different mitochondrial haplotypes. This does not mean, however, that all other half-sib groups we observed were paternal half-sibs. If multiple paternity occurs, all members of the half-sib group must share the same mitochondrial haplotype, as it is maternally inherited. However, paternal half-sibs will also possess identical mitochondrial haplotypes if their mothers share the same haplotype. Therefore, if nested full-sib groups within a half-sib group share the same mitochondrial haplotype, it is impossible to determine which parent they have in common. This lack of resolution typified half-sib group A (Fig. 2), where both nested full-sib groups possessed haplotype 7.

Males entering amplexus and successfully breeding with more than one female in succession is the best explanation for our observation of different haplotypes occurring within a half-sib group. However, this is not the only possible explanation for the phenomenon observed. Spermatozoa can survive for a short period of time in aquatic environments, and may be able to diffuse into nearby egg masses if amplexus is synchronous and pairs occur in close proximity (Laurila and Seppa 1998). However, spermatozoa diffusion has been deemed unlikely in other anurans (Lode et al. 2005; Sztatecsny et al. 2006). Consequently, we do not consider diffused spermatozoa a likely explanation.

This first genetic evidence that wild male anurans are able to reproduce successfully with more than one female offers new insight into anuran breeding systems. Some male *R. pipiens* are able to sire offspring from multiple egg masses in a single breeding season. This suggests that remaining at a breeding site after fertilizing one female's eggs is a good reproductive strategy for males and will increase their fitness, as they are sometimes able to mate with an additional female. This finding also has repercussions for the sampling of any anuran population for genetic study if sampling unrelated individuals is the goal. As the majority of tadpoles captured were related at least at the half-sib level, adults should be targeted to ensure a representative sample of the genetic diversity within a population. It should be noted, however, that the large number of half-sibs in our sample was likely exacerbated by the small size of this population and its isolation from other populations, which would both result in a higher proportion of related individuals than would be found in a large population with gene flow between regions.

Our results also apply to the selection of source individuals to be used in translocation efforts to restore or augment anuran populations if maximizing genetic diversity is a management goal (e.g., Goossens et al. 2002; Moritz 1999; G. A. Wilson et al. 2005). The use of subadults or adults as founding stock is more likely to result in a representative sampling of the genetic diversity present in the source population. However, since survivorship of translocated adults can be low (Dodd and Seigel 1991), obtaining subsamples from many egg masses may maximize genetic diversity in translocated animals while minimizing the effect on the source population.

Acknowledgments.—Thanks to R. Sissons of Parks Canada for sample collection. We thank J. Austin and M. Mahoney for their helpful reviews. Funding for this project was supplied by the Alberta Conservation Association. DWC is supported by an Alberta Ingenuity Scholar award.

A Fluorescent Vertebrate: the Iberian Worm-lizard *Blanus cinereus* (Amphisbaenidae)

DAVID P. MAITLAND

Luminescence is the emission of radiation in excess of thermal radiation (Leverenz 1968). In biological systems there are two main types of luminescence: chemiluminescence (including bioluminescence) which results from biochemical reactions, and photoluminescence (including fluorescence) which results from low-energy photo-excitation (visible light, UV) (Leverenz 1968). Luminescence is found sporadically among different groups of organisms (Herring et al. 1990).

Most of the known bioluminescent organisms are marine, and few are bioluminescent over their entire body surface (Farrant 1997). Bioluminescent terrestrial vertebrates are unknown, but photoluminescencent fluorescence (where UV light is absorbed and re-emitted at longer wavelengths without a detectable afterglow i.e., phosphorescence; Leverenz 1968) is well documented for some vertebrate structures such as parts of bird feathers (Arnold et al. 2002). Among other terrestrial organisms whole-body fluorescence is documented in scorpions (Fasel et al. 1997; Frostet al. 2001), and has not been shown previously in vertebrates (although anecdotal reference is made to this phenomenon in young Western Banded Geckos [*Coleonyx variegatus*] Stahnke 1972; and the blind snake *Leptotyphlops humilis*, Hulse 1971).

We show here for the first time that the Iberian Worm-lizard *Blanus cinereus* (Vandelli) 1797 (Reptilia, Lacertilia, Amphisbaenidae) (Gans 2005) fluoresces blue/green light over its entire body when irradiated by UV radiation.

Materials and Methods.—During our undergraduate terrestrial biology field course a live specimen of the amphisbaenian *Blanus cinereus* was collected (and released after examination) in the Algarve, Portugal, along the sea cliffs of Albuifera at the west end of Praia de Oura Beach during April 2006. Digital photographs were taken using a Canon 1Ds mark II camera (at 16.7 megapixels) in Adobe RGB, 12 bit RAW capture mode at ISO 100 and 400. Macro lenses of 65mm and 100mm focal length and bulb exposure settings were used for fluorescent light capture. White light images were taken using electronic flash. Images were converted and analyzed using Adobe CS2 and RGB pixel values were converted to wavelengths using "*efg's Computer Lab*" "*WaveLengthToRGB*" program in the "*SpectraLibrary.PAS*" available at:

<http://www.efg2.com/Lab/ScienceAndEngineering/Spectra.htm>

Blanus cinereus was found to fluoresce using an excitation wavelength of 368 nm supplied by a portable Ushio ultraviolet lamp, Blacklight Blue (BLB), fitted with a low-pressure mercury-arc lamp code F4T5BLB that emits a narrow band of UV radiation with a sharp spectral peak at 368 nm. Specifications and emission spectra for the lamp are available at:

<http://www.ushio.com/Files/BLBLB.pdf>

Five representative fluorescent regions around the head and body of the worm lizard were sampled for RGB color pixel values (8 bit) using the eyedropper tool in "Info Palette" of Adobe Photoshop CS2. Ten readings were sampled at each of the five regions and the mean (± SD) was obtained from these. Similar measurements were obtained from the central non-fluorescing scale regions, and background (soil) for comparison.

Results.—Blanus cinereus fluoresces with a blue-green light between 437 and 550 nm (mean 465 ± 28 nm; ± SD; N = 5) when excited by UV at 368 nm (Fig. 1). Fluorescence between, and around, scale edges occurs over the entire body but is brightest around the head and tail tip (Fig. 1). A fluorescent scale (brille) covers the eyes (Fig. 1). The polished surfaces of some scales might reflect UV, but we were unable to quantify this (Fig. 1b). No phosphorescence was observed.

Discussion.—The fluorophor (Leverenz 1968) responsible for fluorescence in this amphisbaenian is unknown. However, intact scorpion cuticle fluoresces in the range 440–560 nm (Fasel et al. 1997) as a result of at least two fluorophors; beta-carboline and 7-

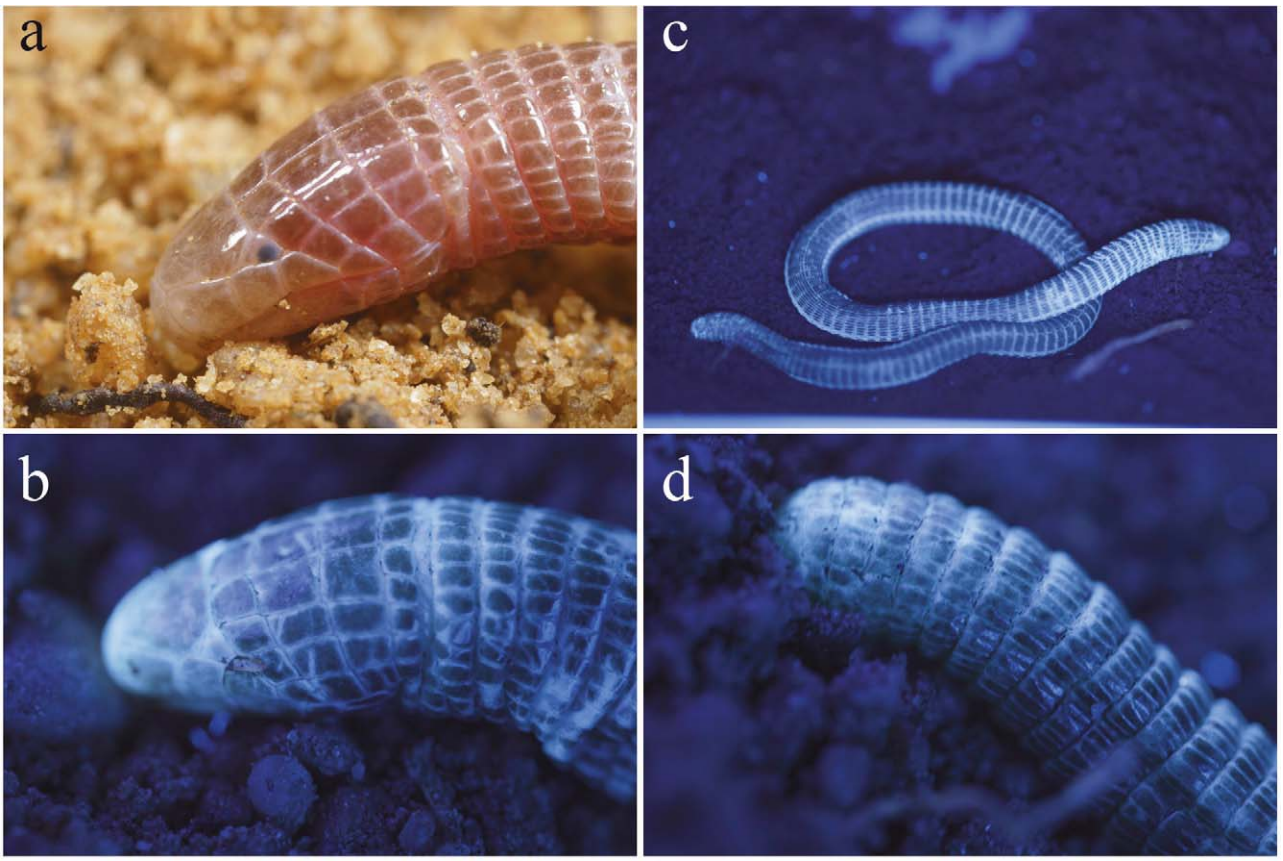

FIG. 1. Fluorescence in the Iberian Worm-lizard *Blanus cinereus* (specimen total body length ~155 mm, 5 mm diameter): a) the head photographed under white light; b) head, c) body, and e) tail, under UV light (368 nm). Photographs by DPM.

hydroxy-4-methylcoumarin, fluorescing at 450 nm and 441 nm respectively (Frost et al. 2001). It is possible, therefore, that scorpions and amphisbaenians possess similar fluorophors.

The function of whole-body fluorescence in *Blanus cinereus* and scorpions is unknown. In scorpions it has been suggested that the fluorophor 7-hydroxy-4-methylcoumarin might act as a block against the UV component of sunlight, because this is a function that coumarins perform in plants (Frost et al. 2001). Another suggestion for scorpions is that the fluorescence might simply be a byproduct of cuticle development in arid adapted organisms (Frost et al. 2001). Indeed, the majority of documented incidences of whole-body fluorescence occurs in invertebrates inhabiting arid environments (Stahnke 1972). Arthropod fluorophors are laid down in the epicuticle as part of the sclerotization process and freshly moulted scorpions and first instar juveniles do not fluoresce (Frost et al. 2001). Thus, whole-body fluorescence in desert-dwelling animals might indicate cuticular adaptations against desiccation and protection against UV radiation; it might not be coincidence therefore, that *Blanus cinereus*, also living in an arid environment and lacking a completely overlapping scale covering, displays whole-body cuticular fluorescence.

Although this report raises many more questions than it answers, further research is warranted. The elucidation of fluorescence in *Blanus cinereus* might lead to the development of new fluorescent tags for DNA and immunological investigations in biochemistry and medicine.

A Protocol for Clearing and Double-Staining Squamate Specimens

JESSICA ANDERSON MAISANO
Jackson School of Geosciences
The University of Texas, Austin, Texas 78712, USA
e-mail: Maisano@mail.utexas.edu

Clearing and double-staining of specimens for bone and cartilage is an invaluable tool for the study of skeletal development and morphology, and published protocols exist that are specific to fish (e.g., Song and Parenti 1995; Taylor and Van Dyke 1985) and amphibians (Hanken and Wassersug 1981). Because none is specific to squamates, the purpose of this paper is to describe a modification of the protocol of Potthoff (1984) that has been applied with excellent results to more than 600 squamate specimens with snout–vent lengths (SVL) ranging from 16 mm (neonates) to more than 120 mm (Fig. 1). For time-sensitive steps, data from previous preparations (Maisano 2000) are provided to allow the user to approximate durations for each step according to snout–vent length of the specimen (Figs. 2–7).

Step 1: Specimens must be formalin-fixed or they will disarticulate. Specimens should be measured (SVL), skinned, and gutted. If a dark peritoneum is present, it should be removed as it will not clear. Specimens are then dehydrated in 95–100% ethanol for a minimum of two days. Remaining steps will be accelerated slightly if conducted on a light table.

Step 2: Specimens are stained for cartilage in a solution of 30% glacial acetic acid/70% ethanol, with enough Alcian blue powder added to approximate the color value of window cleaner. Specimens remain in this solution until cartilaginous elements such as the suprascapular and epiphyseal cartilages are visible through the flesh (Fig. 2). Specimens that dessicated prior to fixation will absorb little or no Alcian blue. When preparing immature (small) specimens, it is important to avoid over-staining as this will make it difficult to detect initial centers of ossification and calcification. When preparing mature (large) specimens, cartilage should be stained an intense blue because the longer duration of subsequent steps will partially leach the stain, making it difficult to see elements that persist as un-mineralized cartilage in adult squamates (e.g., portions of the hyoid apparatus, sternum, etc.). Specimens cannot be re-stained for cartilage after they have been stained for bone (Step 5).

Step 3: Specimens are neutralized in a saturated sodium borate solution for at least 12 h. This step can be used to 'pause' the preparation for up to several days if necessary.

Step 4: Specimens undergo initial digestion in a saturated pancreatin (3X or 4X USP specifications) solution of 65% distilled water/35% saturated sodium borate. Specimens remain in this solution until the limb bones are visible (Fig. 3), and the solution should be changed every two days because it becomes increasingly acidic and the enzyme decreases in activity.

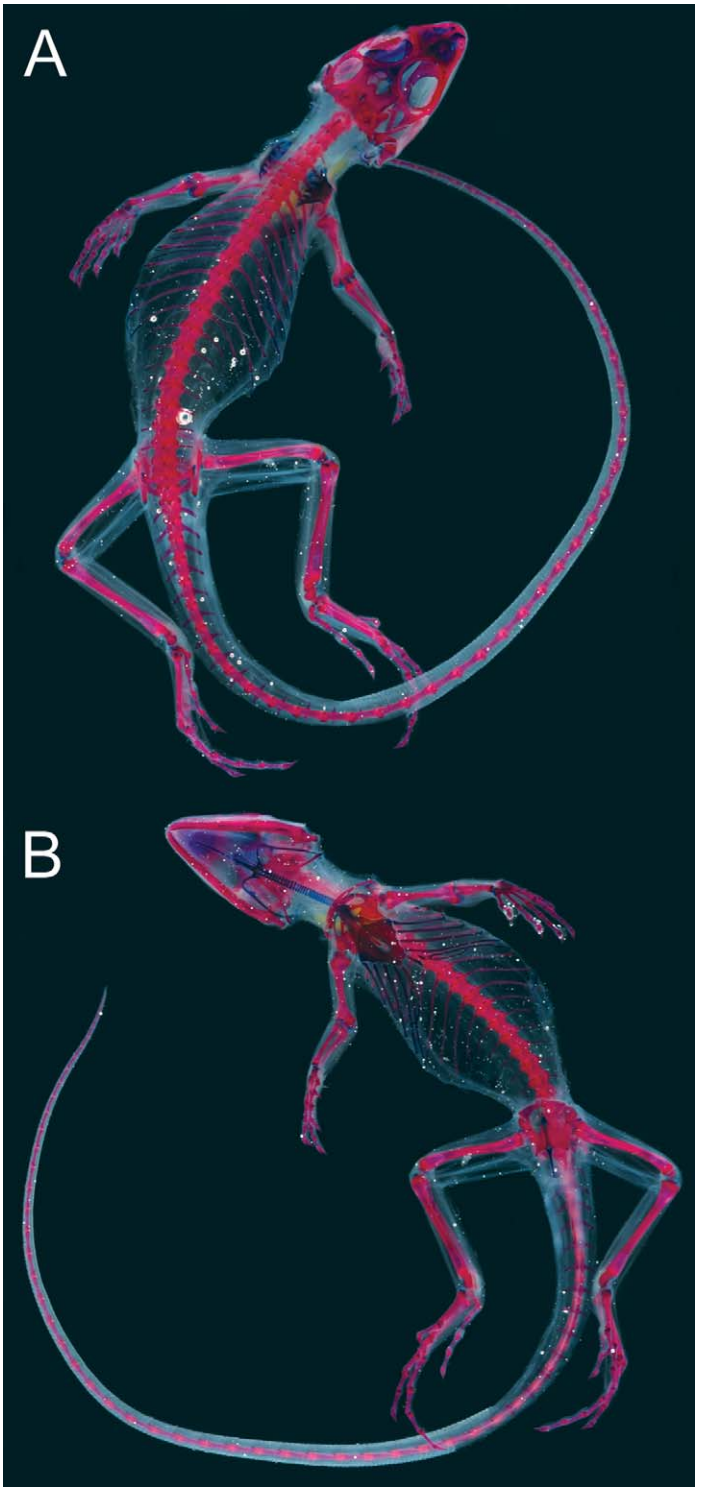

FIG. 1. A) Dorsal and B) ventral views of *Gambelia wislizenii* (Museum of Vertebrate Zoology, MVZ 50268, SVL = 72.8 mm) processed using the protocol described here.

Step 5: Specimens are stained for bone in a 0.75% potassium hydroxide (KOH) solution, with enough Alizarin red powder to make the solution a rich, dark purple. Specimens remain in this solution until their bones are stained a deep, vibrant purple-red (Fig. 4). It is better to over-stain bone rather than under-stain it, as subsequent steps may slightly leach the stain. Specimens may also

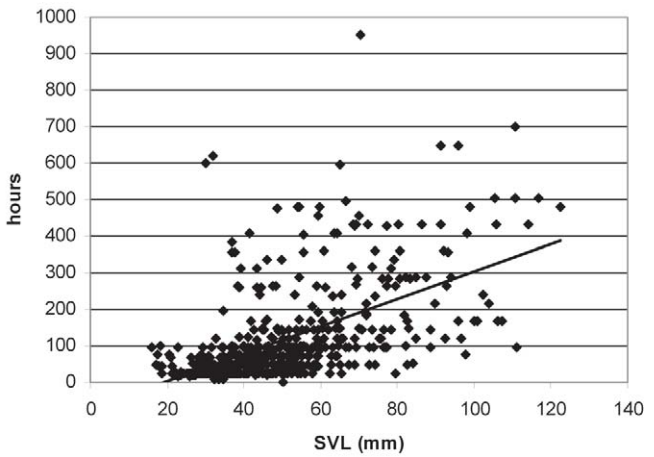

FIG. 3. Time required in first digestion for limb bones to become visible, as it relates to SVL (Step 4).

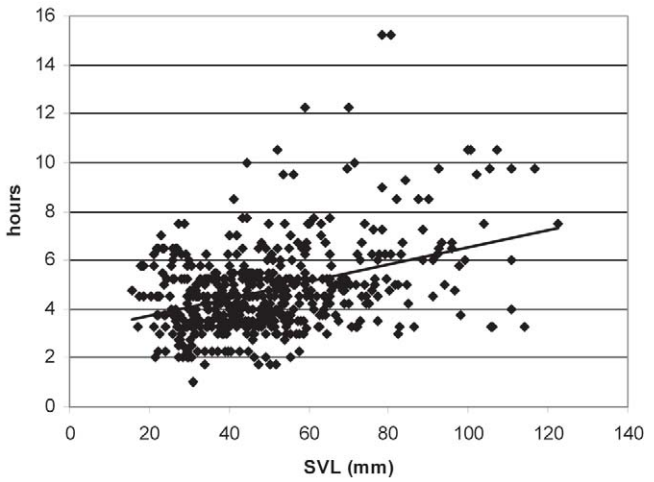

FIG. 4. Time required in Alizarin red stain for bones to stain a vibrant purple-red, as it relates to SVL (Step 5).

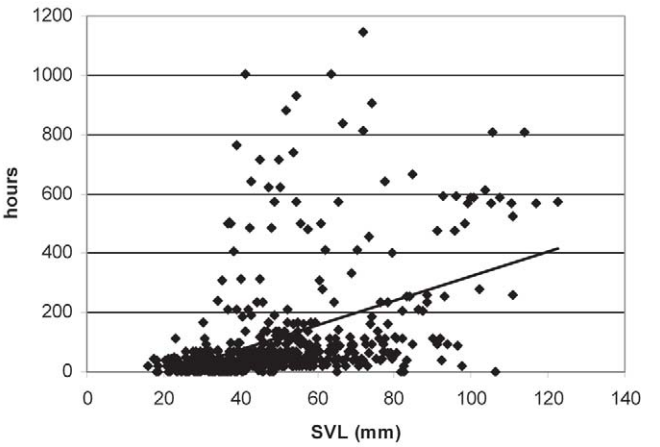

FIG. 5. Time required in second digestion for specimens to become limp, as it relates to SVL (Step 6).

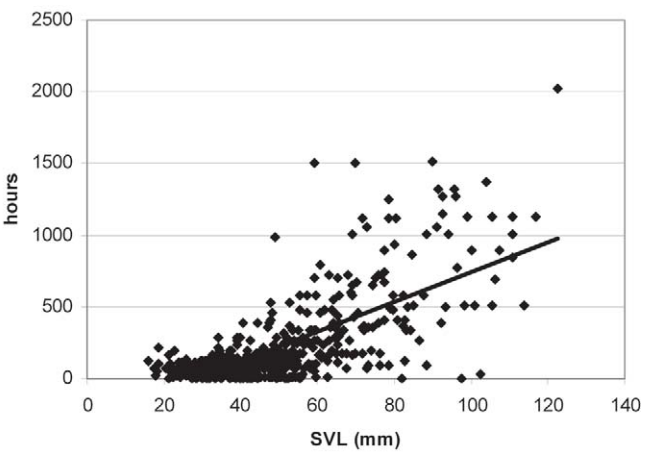

FIG. 6. Time required in first glycerol/KOH clearing solution for all but most resistant areas to clear, as it relates to SVL (Step 7).

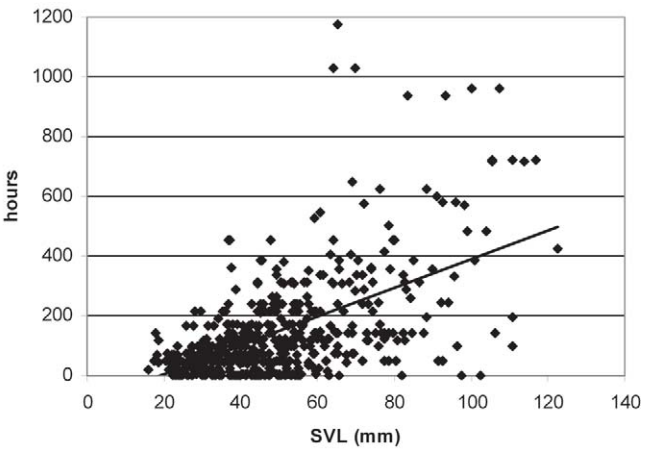

FIG. 7. Time required in second glycerol/KOH clearing solution for clearing to be complete, as it relates to SVL (Step 7).

be re-stained for bone at any time up to the completion of preparation.

Step 6: Specimens are placed in their second and final pancreatin digestion (same solution as in Step 4). Pothoff (1984) recommended that the bulk of the final clearing be accomplished in pancreatin. However, this enzyme substantially weakens the soft tissues, sometimes resulting in disarticulation. Instead, specimens are digested in pancreatin only up to the point where they become limp (i.e., droop when lifted at mid-body) (Fig. 5). Specimens that are already very limp after Alizarin red staining should skip the second digestion as they may begin to disarticulate.

Step 7: Final clearing is accomplished in this step, in two solutions, producing more durable specimens than does prolonged exposure to pancreatin. In fact, specimens will stiffen somewhat during these final steps. Be advised, however, that 0.75% KOH will eventually leach Alcian blue from cartilage, and in very long treatments (large specimens) will lighten Alizarin red staining as well. Specimens are placed in a solution of 30% glycerol/70% KOH until all but the most resistant areas (e.g., neck, base of tail) are clear (Fig. 6). Specimens are then moved to a 60% glycerol/40% KOH solution until clearing is complete (Fig. 7).

Step 8: Specimens are stored in 99% glycerol with a few crystals of thymol added to prevent fungal growth. Specimens should be stored in darkness to prevent fading.

Comparative osteology of small vertebrates has been greatly facilitated by the preparation of cleared and stained whole mounts. This procedure is relatively easy and rapid, especially with the most frequently used method: Alcian blue/ trypsin/ Alizarin red-S clearing and staining technique, as modified by Hanken and Wassersug (1981). This protocol requires the specimens to incubate in trypsin for 16 h or overnight. Trypsin, a proteolytic enzyme, breaks down soft tissues around the bone, after which these tissues are further macerated in KOH. This method produces exquisitely cleared and stained whole mounts. This protocol is used by both developmental biologists and herpetologists who study morphological characteristics.

Unfortunately, there are several disadvantages to the trypsin technique. One is the destruction of soft tissues so that the specimen cannot be used for other purposes, such as histology. Another disadvantage is the possibility of over-digestion, especially of delicate parts such as digits, in both large and small specimens. The length of time needed for the complete clearing and staining of a specimen is approximately 10–12 days, another disadvantage.

Materials and Methods.—We set out to develop a technique that would generate cleared and stained whole mounts of preserved amphibian specimens without excessive tissue destruction and in a faster time frame. This technique employs methyl salicylate and eliminates the trypsin and KOH:glycerol stages.

Formalin-fixed specimens were skinned and eviscerated using caution around the delicate digits. Next, specimens were placed into a solution of Alcian Blue Cartilage Stain 8Gx (20 mg/50 ml) in 3:1 ethanol:glacial acetic acid for 24 h, following the Hanken and Wassersug (1981) technique. This step was followed by two rinses in fresh 3:1 ethanol:glacial acetic acid, each lasting 1 h, and a final rinse in 100% ETOH for 2 h. Specimens were then soaked in several changes of distilled water with the last change sitting overnight to dilute out the ethanol. After being re-hydrated, specimens were transferred 0.5% KOH with 1.5 ml of Alizarin red-S stain from a saturated stock solution for 24 h followed by a rinse in distilled water for 2 h. Usually, several rinses were needed to remove excess stain. Next, specimens were placed into 70% ETOH for 12 h then transferred into two changes of 100% ethanol for 1 h each, followed by a third overnight incubation in 100% ethanol. Specimens were then placed into an appropriately sized vial of methyl salicylate which effectively cleared the specimens within minutes.

Results and Discussion.—Several advantages accompany this technique. This protocol takes 5–6 days to complete, with speci-

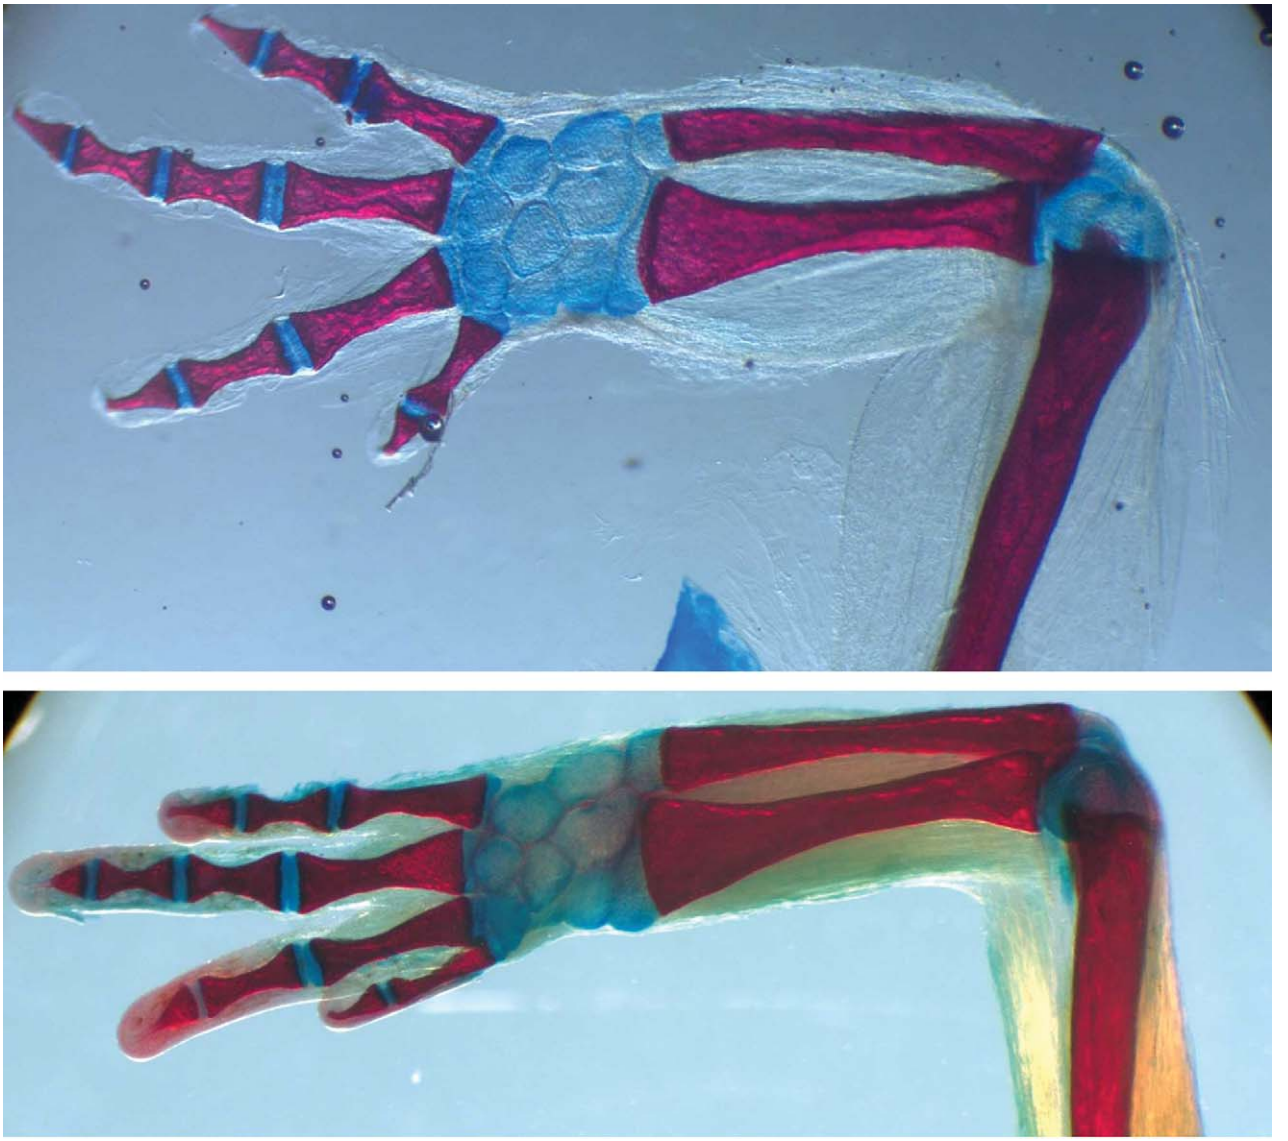

FIG. 1. Photographs showing comparison between a Hanken and Wassersug (1981) cleared and stained specimen (*Eurycea bislineata,* top) and our new approach (*E. bislineata*, bottom).

mens cleared well enough to examine skeletal morphologies (Fig. 1). All of the tissues remain intact and undamaged, and can be removed from methyl salicylate, dehydrated in 100% ethanol, and put back into 70% ethanol for storage. This also allows for histology to be performed on pre-stained specimens with the added benefit of visualizing bone and cartilage. The skinning step can be eliminated for small larvae.

Although this technique works well for specimens under 20 g, it does not clear larger specimens as well as the Hanken and Wassersug (1981) approach. One drop of 30% hydrogen peroxide can be added to approximately 50 ml during the 3:1 rinsings following the Alcian blue staining to aid in clearing any residual pigment left over from the initial skinning and evisceration.

Acknowledgments.—We would like to thank Stanley K. Sessions of Hartwick College for the use of his laboratory and for his advice while modifying this technique.

Measuring the performance of anuran tadpoles under a variety of conditions is a common research theme in herpetology. There are a number of variations in how performance is measured including assessing tadpole survival (e.g., Brown et al. 2006; Loman 2004) or time to metamorphosis (e.g., Holbrook and Petranka 2004). The most often-used variable is the growth rate of tadpoles, measured either as the size of the animals at the end of the experiment (e.g., Pahkala et al. 2003) or by subtracting initial mass from final (e.g., Relyea 2004; Relyea and Hoverman 2003; Rosenberg and Pierce 1995). Rarely though, do researchers measure tadpole mass at multiple times throughout the duration of the experiment, likely due to the time required to perform the measurements or the stress induced upon the tadpoles. Indeed, to do this tadpoles must be weighed by removing them from water and blotting them dry, which if not done quickly, can result in mortality.

In this paper, we describe a novel measure for assessing anuran tadpole growth that is simple, inexpensive, requires minimal removal from water, and is nearly directly correlated with tadpole mass. This measure is therefore useful for obtaining repeated measures throughout experiments without harming individuals. Furthermore, this measure allows for bulk assessments of growth on multiple tadpoles at once if time is limited, or if large numbers of individuals are involved.

Our method involves the use of image analysis, whereby digital photographs of specimens are taken and computer software used to measure features of the specimens (Davis et al. 2004; Davis et al. 2007; Davis and Grayson 2007; Davis and Maerz 2007). Variations of this technique are already frequently employed by herpetological researchers interested in tadpole shape (Relyea 2004, 2005; Relyea and Hoverman 2003; Van Buskirk 2002; Wilson et al. 2005), though to our knowledge, this technique has not been used to assess growth rates or directly compared to other measured of size. We therefore set out here to determine if this technique could be used to assess tadpole size and if this measure of size was related to traditional mass measurements. There were two components to this research. First, we examined a set of lab-reared tadpoles that varied in size, using traditional (tadpole mass) and the image analysis size measures. Second, we employed this technique to measure tadpoles that were being raised in an ongoing, unrelated experiment to evaluate its utility in the field.

For our first component, we obtained egg masses of *Rana sylvatica* from Habersham Co., Georgia during February 2006 and divided them into four tubs in the lab where they hatched. Tadpoles were fed ad libitum thereafter with a powder, ground from a 60:40 ratio of rabbit food pellets to Reptomin floating aquatic turtle sticks. Two weeks later there was a natural range of tadpole sizes in each tub. At this point we haphazardly caught single individuals from each tub with dip nets and placed them each in a standard plastic weighing dish filled with water from its tub. The dish was then photographed from above with a Canon Powershot G6 digital camera that was mounted on a mini copy stand at a fixed distance from the specimens (Fig. 1A). Care was taken to ensure that the tadpole was not moving at the time of the photograph (to avoid blurring), and that its dorsal surface was fully in view. After photographing, the tadpole was removed from the dish, blotted dry and weighed on an electronic balance. This was repeated until 58 individuals were processed. Throughout the experiment, we made an effort to capture tadpoles that varied in size. We also photographed a standard metric ruler to provide a calibration image for the image analysis software (see below).

To measure the tadpoles we imported all digital photos into an image analysis program, Fovea Pro (Reindeer Graphics, Inc.), used previously to measure features of herpetofauna (Davis and Grayson 2007; Davis and Maerz 2007). We first calibrated the software using the ruler image so that the pixel-to-millimeter ratio could be retained for the tadpole images. For each tadpole image we digitally selected the entire tadpole (head and tail), which was made easier by the fact that the tadpole was darkly colored on a white background (Fig. 1B). A Fovea Pro measure routine was then initiated, which measured the total surface area of the selection, which in this case was the surface area of the tadpole (43 mm^2 in Fig. 1B). This surface area measure was the unit of 'tadpole size' for our analyses. Once all images were measured we compared the tadpole surface area data (log-transformed) to the mass data (log-transformed) using Pearson Correlation. There was a highly significant positive relationship between individual tadpole mass and our surface area measure ($r = 0.996$, $p < 0.001$; Fig. 2).

Because a tadpole's body is relatively spherical, one might expect a curvilinear (e.g., exponential) relationship between tadpole dorsal area and mass, and therefore be surprised by the strong linear correlation we observed. However, the minimum and maximum tadpole area measurements were 18 and 200 mm^2, and the relationship between dorsal area and volume [mass] is relatively linear between these values. The relationship would only be significantly curvilinear if extended to the origin and out well beyond 200 mm^2, but a tadpole never has zero area or mass, and is not infinitely large.

In the second part of this project, we tested the utility of this technique while conducting an unrelated experiment that involved monitoring the growth of tadpoles within 18 plastic 55-L tubs. Each tub contained 50 tadpoles of *Rana sylvatica*, and our goal was to measure the average size of tadpoles within each tub with minimal mortality. On the day of sampling, the camera and photographing stand were set on a portable table next to the tubs (as in Fig. 1A). Ten tadpoles were dipnetted from the first tub and placed into two large petri dishes (5 in each) along with water from their tub. When the tadpoles settled, a photograph of each dish was obtained as described above. The tadpoles were then released back to their respective tubs. This process was repeated until all tubs had been sampled. During this process we recorded the time to sample (i.e., dipnet and photograph 10 tadpoles) each tub, as well

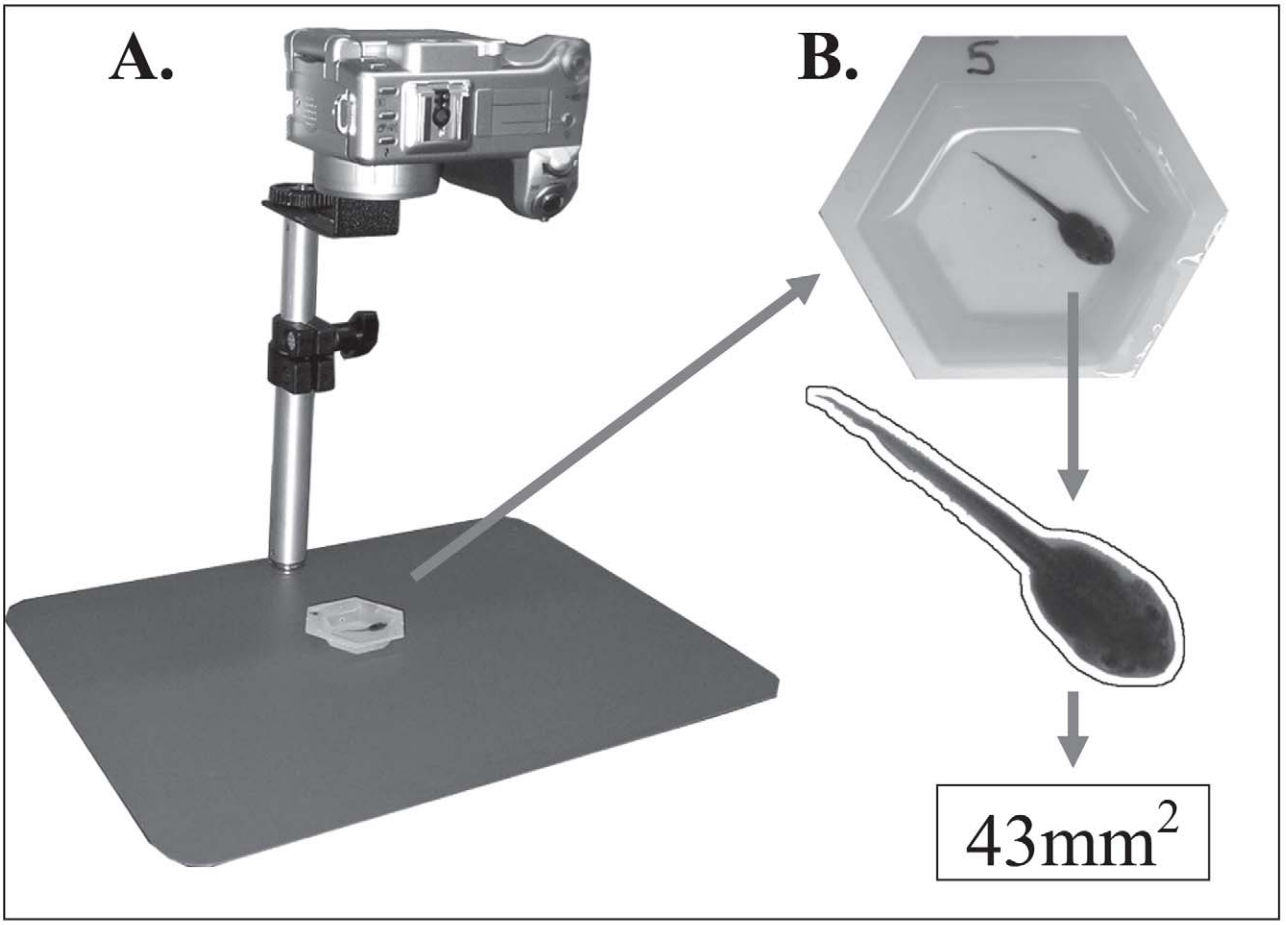

FIG. 1. Camera and photography stand used to photograph tadpoles in the lab and field (A). Tadpoles were held in white plastic weighing boats filled with water during photography. Later, digital images of tadpoles (B) were examined using Fovea Pro software. In the program, the entire tadpole was selected and its dorsal surface area measured in mm^2 based on a previously defined pixel-to-mm ratio obtained from a ruler image.

as the start and end times for the entire session. On average it took us approximately 2 min to sample the ten tadpoles per tub, with all 18 tubs finished in 48 min. In the lab, the same procedures were used to obtain size data from all individual tadpoles in the images as described earlier.

In the procedure described here, tadpoles are dipnetted and immediately placed in a dish of water for photography, they remain in this dish for no more than 2 min, and then are released back into their original water. Thus, tadpoles are subjected to minimal stress because they are never long out of water during the procedure. This technique can be used in the lab or field, and in both situations, large numbers of tadpoles can be quickly and non-invasively sampled, and sampling can be done multiple times over the course of experiments. Further, the measure of size we obtained for each tadpole (its surface area) was nearly perfectly correlated with tadpole mass (Fig. 2). Moreover, although not explored here, it is also possible to generate measures of body and tail length from the tadpole images (or the ratio of both). We also note that while the software used here costs ~ $ US800, there is a freely available image analysis program (ImageJ — http://rsb.info.nih.gov/ij/) that can perform the same tasks as outlined here. Thus, the method we describe is arguably faster and safer than mass measurements, and

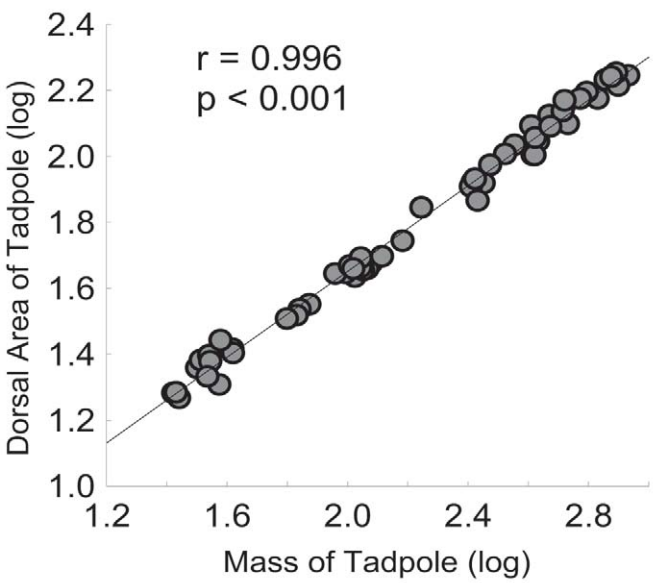

FIG. 2. Comparison of dorsal surface area measurement (log-transformed), obtained from image analysis procedure, and log-transformed mass of 58 lab-reared *Rana sylvatica* tadpoles.

allows for a wider range of data to be measured during experiments.

Acknowledgments.—We thank Daniel van Dijk, Alina Ruiz, and members of the University of Georgia 2006 Herpetology class for field and lab assistance. Tadpoles were captured and raised with approval of the Institutional Animal Care and Use Committee of the University of Georgia.

Anolis lizards, or anoles, are a model system for evolutionary biology (e.g., Emerson 2002; Losos 1994), behavioral and physiological ecology (e.g ., Huey et al. 2003; Irschick and Garland 2001; Lovern et al. 2004; Stamps 1983), community ecology (e.g., Pacala and Roughgarden 1985; Schoener 1968), toxicology (e.g., Burger et al. 2004), and physiology and neuroendocrinology (e.g., Greenberg 2003; Wade 2005). Because the genome of *Anolis carolinensis* has recently been sequenced (http://www.genome.gov/Pages/Research/Sequencing/SeqProposals/GreenAnoleLizardAmericanAlligatorSeq.pdf), work on this genus is expected to expand as it becomes more accessible to new disciplines such as developmental and statistical genetics, comparative genomics, and the biomedical sciences. For this reason it is imperative that methods for working with *Anolis* be developed to facilitate comparisons between studies and assure the ethical treatment of these animals as they are used by researchers not accustomed to working with reptiles.

The goal of this manuscript is to describe methods for the maintenance of captive breeding colonies of *Anolis* species. The general characteristics of a species that must be considered to maintain healthy breeding populations include its availability (in the wild or the pet trade), physiological needs (e.g., temperature, humidity, nutrition), and sociality (density of housed individuals) (Greenberg 1992). These factors also must be independently considered for the care of juveniles to assure their proper growth and development. In addition to species-specific factors, practical limitations such as available space, number of species to be housed together, and available resources (incubators, cage washers, climate control systems, etc.) must be considered when developing protocols for the maintenance of animals in captivity. These likely vary greatly from institution to institution. A broad perspective on the general use of reptiles for research can be found in Greenberg (1992) and Pough (1991) and on reptilian egg incubation in Deming (2004).

Here we describe the detailed methods we have found to be successful for the care and maintenance of 13 *Anolis* species from southern Florida and four Caribbean islands that inhabit a wide

range of microhabitats. While we have worked primarily with *A. sagrei*, *A. carolinensis*, and *A. cristatellus*, we also have experienced success breeding *A. chlorocyanus*, *A. coelestinus*, *A. cybotes*, *A. distichus*, *A. evermanni*, *A. grahami*, *A. gundlachi*, *A. krugi*, *A. lineatopus*, and *A. valencienni*. Lovern et al. (2004) provided protocols for *A. carolinensis*, the northernmost species of the genus. We have modified these protocols to fit the needs of an additional 12 species. The methods we describe here are readily amenable to larger-scale laboratory settings where large numbers of animals from different species are maintained. We successfully raised all species through the F1 generation except for *A. cristatellus*, which we raised through the F2 generation. We developed these methods under the guidance of Washington University's animal facilities management (J. Diani), veterinary services, and the Institutional Animal Care and Use Committee. Based on explicit calculations of the effort and expense needed to care for these lizards (space, lighting, climate control, basic daily care, etc.), we were charged $0.16 per lizard per day to maintain these lizards in our animal care facility.

The key factor in developing protocols for the maintenance of captive breeding colonies is an understanding of a taxon's natural history. Anoles are remarkably variable in their natural history, ecology, behavior, and physiology. They inhabit a broad variety of habitats from hot xeric semi-deserts to cool montane rainforests, ranging from the equatorial forests of South America throughout the Caribbean Islands and into southeastern North America. Caribbean anoles, including populations found in the southern United States, breed from early spring through late-summer depending on the temperature and humidity of a given year (Licht and Gorman 1970). Mean field body temperatures range from 21.0–33.0°C (Clark and Kroll 1974). Some species narrowly regulate their body temperature by basking, whereas others are thermoconformers; furthermore, within a species, mean body temperature changes with altitude and season (Hertz 1981; Hertz and Huey 1981; Huey and Webster 1976; Ruibal 1961). Although fewer field data are available, similar observations are made regarding interspecific variation among anoles in their hydric environments (Hertz 1980, 1992), size at reproductive maturity, hatchling size, and growth rate (Kobayashi et al. 1983; Michaud and Echternacht 1995). In some cases, physiological differences observed among populations or even species may represent phenotypic plasticity, rather than genetic differences (e.g., Wilson and Echternacht 1987, 1990). Given these many and varied differences, there is no one-size-fits-all prescription for caring for and raising anoles; rather, to the extent possible, husbandry needs to be tailored to the biology of each species.

For the following discussion, it is important to note that many of the species we have maintained in captivity occur primarily in open, sunny habitats (but see Interspecific Variation below). Such species often thermoregulate actively and maintain relatively high body temperatures; moreover, they tend to be less sensitive to water loss than many other anoles (Hertz 1981, 1980, 1992). Because the species we have used in our research naturally occur in the Caribbean and southeastern United States, we chose mean conditions for humidity, moisture, and light based on climatic data in those regions for the months of peak breeding, April to June (for Florida and southeastern United States: Hamlett 1952, Lee et al. 1989, TJS pers. obs.; for the Caribbean: Jenssen and Nunez 1994).

Husbandry and Egg Collection

We have collected adults of each species from the wild or, for species found within the United States, purchased them from professional reptile vendors. Select species are also available from the pet trade; however the history and genetics of these individuals are not typically known. Occasionally, new animals in the lab do not breed or deposit eggs at first, but after two weeks, individuals generally show no visible signs of distress (as described in Greenberg 2002, 2003) and breed regularly. Wild-caught anoles commonly host parasitic mites, often found on the dewlap, groin, base of the tail, or axillae. Although specific host-parasite relationships likely exist between mite and lizard species from the same island, lizards may be more severely affected by novel parasites introduced from other locations. Because we do not have space to house each lizard species in its own room, lizards from different islands must be kept together. Consequently, upon arrival to the animal care facility, we remove all mites using forceps and treat the lizards with commercial de-miting solution as described by the manufacturer (Reptile Relief, Natural Chemistry). Endoparasites may be problematic as well. For example, we have discovered infestations of endoparasitic worms as tumor-like growths on the joints and jaws in wild-caught *A. cybotes* and *A. cristatellus*. We immediately cull individuals from our population as soon as a growth is detected to limit the spread of this parasite between individuals. Sarcophagic fly infestations are also common in some populations of wild-caught anoles (Irschick et al. 2006). We do not prophylactically treat for viral or bacterial infections.

To establish breeding groups, we kept three or four adult females (depending on size) and one adult male together in a standard rat cage (42 cm length × 27.5 cm width × 21 cm height, Ancare Corp.) with oak sticks collected from the outdoors to provide perches (Fig. 1). Before using the sticks as perches, we sterilize them with one cycle of a standard cage washing machine at 180°C. These sex ratios are within the range of those found in the wild for *A. carolinensis* (Jenssen and Nunez 1998) and in many species, several female territories occur within the territory of an adult male. This creates a breeding regime in which juveniles from each cage are half-sibs in genetic analyses, with known father and unknown mother. However, anoles are known to store sperm (Fox 1963; Licht 1973) for many months, so if females were reproductively mature when captured, one cannot assume that the male in the cage fathered the offspring; molecular testing is needed to verify that conclusion.

To prevent escape, we place screen mesh inserts in the cage tops rather than the cloth filter tops typically used when housing mice (New York Wire, mesh 16 × 84 inches). We cover cage bottoms with synthetic cage carpet (ReptiCage Carpet, ZooMed). Cage carpet is readily available, can be easily cleaned and sterilized, and is reusable. The carpet also holds moisture raising the humidity within each cage. We have avoided the use of gravel or sand as a cage substrate because we found that smaller individuals ingest these substrates and become impacted. We discovered that wood chips and sphagnum moss promoted fungal growth after a short time, needed to be changed often, and are not reusable. We clean and sterilize cage carpet and perches approximately once each

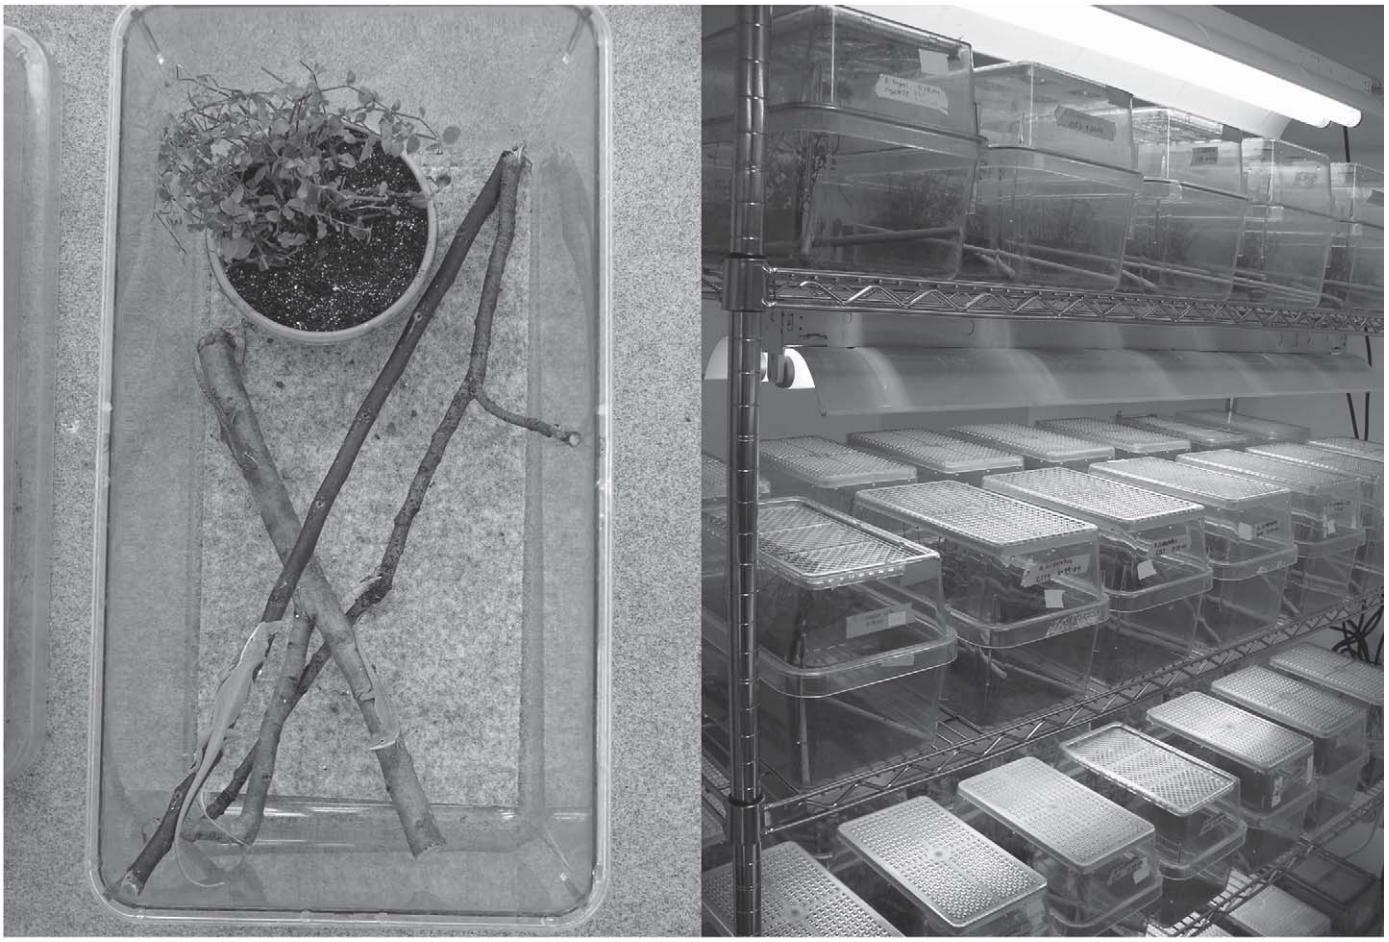

FIG. 1. A) A typical breeding cage for *Anolis*. Note the potted plant, cage carpet floor, sticks to act as perches, and several females held with one male. B) A typical rack of juvenile cages. Note the proximity of the UV lights over each row of cages.

month by soaking them in T.B.Q. disinfectant solution (Steris) while cages are washed using a cage washing machine. Anoles may exhibit "cage-novelty induced stress" when placed in unfamiliar conditions and thus perches and carpet should be exchanged separately so as not to return a lizard to a completely novel cage setting after cleaning (Greenberg 1992; Morgan and Tromborg 2007). Opaque cage dividers separate the cages to limit intraspecific male aggression. In cages not separated by cage dividers, males tend to develop open sores on their snout as they attempt to fight with males in adjacent cages. We recommend labeling each cage with the species name, locality of the collection, origin (wild caught or captive bred), date entered into the facility, number of individuals in the cage, and when applicable, age of the individuals and parentage information.

We maintain room temperature, humidity, and photoperiod using an automated climate control system (METASYS, Johnson Controls), cycled seasonally to mimic natural coastal Caribbean wet and dry season fluctuations. During the summer months room temperature cycles daily with a 28°C day, 25°C night and a constant 60–65% humidity. We mist each cage twice daily, raising the humidity within each cage to approximately 85% and supplying the animals with substantial drinking water. Relatively low humidity (less than 35%) is known to retard ovarian growth in *A. carolinensis* (Summers 1988). We also keep a small potted plant in each cage to help maintain relatively high levels of humidity between misting times. During the winter, we drop the room's humidity to approximately 50% and lower the temperatures by 1–2°C. The cages are still misted twice daily during this time. We keep light cycles at 13 h light/ 11 h dark cycles during the summer months and gradually shift to 11 h light/ 13 h dark cycles from early October though late March, approximately simulating the light cycles of the Caribbean. We light the room with both standard fluorescent ceiling lights and 15–20W fluorescent UV bulbs (ReptiSun 5.0) set directly over each cage. To simulate dawn and dusk we turn the ceiling lights on or off 30 minutes before or after the UV lights respectively. In the absence of an automated climate control system these conditions can be maintained with cost-effective, widely available alternatives such as electric timers, standalone humidifiers, and heat lamps (see Bartlett and Bartlett 2001; Hunziker 1994; Lovern 2004 for several more alternatives).

We feed adult anoles a diet of crickets twice weekly, sized appropriately for the species. Crickets are purchased from Timberline Fisheries Corp. (Marion, Illinois) sold in standard English units of 0.25," 0.5," or 0.75." To supplement the lizards' nutrition we dust crickets with a 1:1 mix of commercial vitamin supplement and a calcium additive (Rep-Cal brand Herpvitive and Cal-

cium Supplement) every other feeding. To maintain our cricket colony, we feed the crickets a diet of Laena Poultry (Purina) *ad libitum*. Be aware that some cricket suppliers regularly feed their animals diets that will be transferred to the lizards and may influence a specimen's growth or experimental results. For example, some cricket suppliers prophylactically administer antibiotics to their crickets. During our study of skeletal development (TJS), we found signs of the calcium chelator, tetracycline, in developing long bones. Tetracyclines are known to retard bone growth in many mammals, and thus we may have inadvertently compromised our experiment on bone growth by indirectly feeding it to lizards. We recommend inquiring into the treatment of lizard food when it is purchased from a commercial supplier.

To facilitate the collection of eggs, we supply each cage with a small leafy plant potted in a disposable plastic container (*Ziplock Snap and Seal*™, medium bowl or equivalent). Anoles lay one egg from alternating oviducts every one to four weeks (Andrews 1985; Andrews and Rand 1974; Hamlett 1952). We collected eggs every one to three days by removing the plant from the cage, removing the plant from the pot and thoroughly sifting through the root ball and potting substrate. Female anoles lay eggs at all depths in the pot. To ensure that eggs are not missed during collections, we completely remove the potting substrate from the container and search it by hand. Because female anoles can retain their eggs during times of drought (Socci et al. 2005; Stamps 1976), we remoisten the soil after each egg collection. When females are first brought into captivity, they may take some time to begin laying eggs in the potted plant. Initially, eggs may be laid on the cage bottom where they rapidly desiccate.

Viable eggs are generally white and range 0.5–1.5 cm in length. We clean eggs of excess soil using forceps or by hand and transfer them to a standard tissue-culture dish (100 mm × 20 mm) packed with moist, coarse-grained vermiculite, 1:1 vermiculite to de-ionized water by weight. We then cover the dish with its lid, secure it with *Fisherbrand* labeling tape and incubate at 27°C and ~75% humidity for 10–14 days. At this time, we remove the lid and cover the dishes with fiberglass screening to facilitate gas exchange (New York Wire, mesh 16" × 84"). We cut the screening into 15 cm squares and secure it around the circumference of the dish with rubber bands. We restack the dishes in the incubator in such a way that each dish acts as the cover for the dish below it. The top dish is loosely covered with its original lid and the weight of each dish is recorded. We then reweigh the dishes every one to two days and rehydrate them with drops of de-ionized water until the dish is returned to its initial weight. Additionally, to limit the evaporation from the culture dishes, we keep a pan of de-ionized water in the incubator.

Eggs of many squamates are highly permeable and actively exchange water and gas throughout embryonic development. Eggs not relatively free of debris will often desiccate or the embryo will die leading to fungal growth on the egg's surface (PMH, pers. obs). A fine balance also exists between the water within the egg and that in the surrounding substrate (Ackerman and Lott 2004). If the substrate is drier than the egg, the egg will lose water and desiccate. Inversely, if the egg is drier than the substrate, water will flood the egg, possibly damaging the embryo due to increased pressure. While these scenarios represent the extremes of a vast continuum, water balance in reptilian eggs is known to influence many developmental processes (e.g., Packard et al. 1999, 2000) and care should be taken to keep these conditions stable between species and throughout the period of development. Anole species living in different environments probably have adaptively differentiated in their ability to withstand humidity and desiccation, but this has been little studied (Andrews and Sexton 1981).

Care for Juveniles

For the 13 *Anolis* species we have bred in the laboratory, eggs hatch between 25 and 42 days from the date of laying. Upon hatching, we remove juvenile lizards from the culture dish and place them in a standard mouse cage (26 × 20.5 × 15.5 cm, Ancare Corp.) with conditions as described above. We immediately mist hatchlings with water (for drinking and to remove vermiculite stuck to their bodies) and feed them flightless *Drosophila* maintained in a stock culture. As individuals mature, we gradually transfer them to a standard cricket diet. Crickets are chosen by size: smaller lizards, ~2.5cm to 4.0cm SVL, are fed smaller crickets, "pinhead" to 0.25". We later transfer juvenile anoles larger than ~4.0 cm to a diet of larger crickets, 0.5", by adding crickets of both sizes to the cage for approximately one month. We only feed the largest crickets, 0.75", to cages with adult males greater than 5.0 cm SVL. Because we occasionally observed crickets feeding on juvenile lizards, we remove uneaten crickets from the cages within several hours of feeding.

Lizards raised without substantial social interaction throughout juvenile development rarely breed during adulthood (MAJ, pers. obs.); however, housing juveniles individually may be desirable for some studies (e.g., tracking individual growth). In this case, juvenile lizards can be allowed limited social interaction by removing cage dividers to provide visual access to the neighboring cages. Preferably, juvenile lizards would be housed in groups of three to five individuals per rat cage when individual records are not necessary or when marking individuals (e.g., Ferner 1979; Fisher and Muth 1989; Johnson 2005) will not interfere with an experiment. In this case however, the more dominant lizards tend to capture more food, leading to size disparity within each cage (PMH, pers. obs). As animals become dominant, especially males, they can be removed from the group cage and housed separately.

Captive-bred juvenile lizards often face problems during shedding. Lizards often encounter the most difficulty shedding the skin around the head, legs, and cloacal regions. On the head, unshed skin can block eyes, cover nostrils and impede feeding. Around the legs, excess skin can constrict and reduce circulation leading to the occasional loss of limb elements. Unshed skin around the cloaca can cause complications during excretion and promote infection. To prevent these complications we often removed unshed skin on juvenile and adult lizards by moistening the skin with warm water and then gently removing it with fine forceps. Care should be taken not to injure sensitive areas while removing unshed skin.

Embryo Collection

Anolis embryos of all stages can be dissected from eggs under a dissecting microscope. To do so, we remove eggs from their culture dish and submerge them in phosphate buffered saline solution (PBS; Sambrook and Russell 2001). While illuminating the

egg from the side, we then position the egg with the embryo upwards by locating its shadow beneath the shell. Using #5 watchmaker's forceps, we make a small incision outside of the darkened area and extend it, with shallow incisions, across the top of the embryo. Folding the shell away, the embryo is then visible lying on its left side within the yolk and can be easily removed from the yolk and surrounding amnionic membrane. For young embryos, adding a drop of 10% bovine serum albumin to the Petri dish may help in the removal of extra-embryonic membranes. We preserve young embryos by immediately submerging them in 4% paraformaldehyde PBS in a plastic centrifuge tube, incubating overnight at room temperature, and finally transferring them to 70% ethanol. This method of fixation is useful for many basic histological techniques such as gross examination of both soft and hard tissue. Additional measures may be needed for analysis of gene expression or other molecular or immunochemical assays. To assure the humane treatment of embryos approaching hatching, we euthanize these animals with an IP injection of xylazine (20 mg/ml) prior to fixing. Xylazine (Rompun**,** Bayer) is a non-narcotic anesthetic commonly used on mammals. We fix late-stage embryos in 10% buffered formalin for 24 h, and then move them to 70% ethanol. We have observed that *Anolis* embryos tend to adhere to "soft" polystyrene tubes during fixation and cannot be removed without damage. We prefer to use common polypropylene 15 ml conical tubes (i.e., Corning, FisherBrand) when preserving embryos for use in histological preparations or 2 ml centrifuge tubes when preserving embryos for long term storage.

Interspecific Variation

Although the methods described above have been successful for the majority of *Anolis* species we have examined, interspecific differences have required minor adjustments in our protocol. For example, most well-studied species of Caribbean *Anolis*, including the majority of species for which these methods have been utilized, occur in sunny, open areas. The temperature and humidity simulated in our animal care facilities reflect these microclimatic conditions. However, *A. gundlachi* and *A. krugi* are two species that occur in the montane rainforest of Puerto Rico. *Anolis gundlachi* occurs in the cool, deep shade of the forest, and *A. krugi* is typically found in shaded habitats, moving into the sun at higher elevations (Hertz 1992; Rand 1964; Schoener and Schoener 1971; Williams 1972). These habitats offer a very different climate than sunny, open habitats. In our work, after a number of *A. gundlachi* eggs died before hatching when incubated at the standard 27°C (i.e., no eggs from this species survived to hatching), we placed 4 *A. gundlachi* eggs in a 25°C room immediately after being laid. Three of these eggs then produced live hatchlings one month later. In addition, only 17 of 64 *A. krugi* eggs (25%) survived to hatching, but incubating these eggs at a lower temperature may have increased survivorship substantially. For this reason, we recommend matching the cage and egg incubation temperatures and humidity as closely as possible to the natural microclimates of the species for optimal breeding results. Moreover, we note that a comparative study on the thermal biology of anole eggs could prove very interesting.

Additionally, not all species of *Anolis* lizards exhibit the same egg-laying behavior. *Anolis valencienni* is a species that, at least occasionally, lays eggs communally in sites such as tree holes or bromeliads well above the ground (Rand 1967). We have observed that almost all female *A. valencienni* held in captivity do not bury their eggs in the potted plants initially, but instead deposit them on the cage carpet, adhere them to perches, or leave them on the soil surface. To collect viable eggs from this species, we found it necessary to check for eggs every day, particularly in the late evening. However, individuals that have been in captivity for longer times, typically greater than nine months, do begin to deposit their eggs in the pots; after two years in captivity, all eggs are found buried in pots. In the future, we plan to examine whether this species will preferentially lay eggs in an artificial cavity if one is provided in the cage. Whereas the other *Anolis* species we have studied have a mean incubation time of about 29 days, *A. valencienni* also appears to have a considerably longer mean incubation time of about 42 days when incubated under similar conditions.

In conclusion, basic knowledge of the reproductive biology and ecology of a species is necessary to establish successful breeding colonies of lizards. Further consideration of variation among species' ecology may allow for optimization of these methods for species from different habitats. Fortunately for anoles, a substantial body of literature exists on the natural history of many species in this genus, further supporting the utility of these lizards as a model system for a great diversity of research questions.

We have successfully maintained breeding colonies and collected embryos from a diverse collection of *Anolis* species. The above protocols should allow researchers with even a basic animal care facility to breed *Anolis* and collect their embryos for use in standard analyses.

Acknowledgments.—We would like to thank the animal care technicians C. Deggendorf, M. Kwiatkowski, G. McMurray and D. Piatchek for their dedicated attention to these lizards. S. Echternacht, M. Lovern, and J. Stamps gave valuable recommendations for our protocols when beginning our research. J. Kolbe, M. Edgar, and P. Taylor also provided useful feedback on these protocols. Special thanks go to L. Revell and for his careful attention to the animals' well-being and many useful discussions regarding these protocols. We would also like to thank the many undergraduates who have helped optimize these protocols and have ensured the daily care of our lizards, especially S. Barrett, J. Bayers, C. Fresquez, P. Garner, J. Tarsi, and S. Wang. The Washington University Institutional Animal Care and Use Committee formally approved all of the methods described in this paper. Funding for the collection and maintenance of these colonies came from a generous grant from the David and Lucile Packard Foundation and NSF DEB0519777.

A Notching System for Marking Softshell Turtles

MICHAEL V. PLUMMER
Department of Biology, Box 12251
Harding University, Searcy, Arkansas 72143, USA
e-mail: plummer@harding.edu

Beginning with Cagle (1939), the marginal scutes of the turtle carapace have often been used for various marking systems on hard-shelled turtles (reviewed in Ernst et al. 1974; Ferner 2007; Plummer and Ferner, *in press*). Because the carapacial margin of trionychid turtles lacks discrete scutes, these turtles present difficulties for unambiguously marking a large number of individuals; thus a systematic marking system for softshells is needed. Herein, I describe a system used in two softshell population studies (Plummer 1977a, 1979). Plummer (1977a) made at least 2300 captures of 1500 marked *Apalone mutica* over a 3-yr period. A long-term population study of *A. spinifera* by Plummer and Mills (*in press*) was based on 570 captures of 270 marked turtles from 1994–2003 and this study continues today (716 captures of 322 turtles as of 2007). Although the marking method was briefly mentioned by Plummer (1977a, 1979), details were not provided.

Marks are made by cutting triangular-shaped pieces from the edge of the carapace using a pocketknife for adults and juveniles and small scissors for hatchlings. Alternatively, a paper hole punch may be used to apply marks (Doody and Tamplin 1992). A small amount of bleeding may follow marking because the shell is vascularized. The depth of the notched cut varies with turtle size, approximately 15–25 mm for adults and 8–12 mm for juveniles. The notches eventually heal and fill to the original carapacial edge; however, the triangular pale scar tissue remains evident. The numerical marking scheme is based on 12 h clock positions. From a dorsal view, the face of a clock is superimposed on the carapace (Fig. 1). Distinct positions are 12 and 6 (opposite each other on the midline of the carapace), 2 and 10 (just anterior to the bridge), and 3 and 9 (opposite each other but perpendicular to the midline. Positions 4–5 and 7–8 are less precise but positioned between unambiguous positions (3, 6, and 9).

To mark a turtle, one to five notches (notching groups 1–5) are cut in the edge of the carapace. Turtle nos. 1–12 are identified by one notch; nos. 13–78 by two notches; nos. 79–142 by three notches; nos. 143–195 by four notches, and nos. 196–238 by five notches (Fig. 1). Within a notching group (Fig. 1 B–L), numbers are consecutive by progressing from last notch clockwise. For example, turtles no. 13–23 are marked as follows: turtle no. 13 has notches at the nos. 12 and 1 positions, turtle no. 14 has notches at the 12 and 2 positions, etc., to turtle no. 23, which has notches at the 12 and 11 positions (Fig. 1B). For a four notch example, turtle no. 181 has notches at the 5, 6, 7, and 8 positions, turtle no. 182 has notches at the 5, 6, 7, and 9 positions, etc., to turtle no. 185, which has notches at the 5, 6, 7, and 11 positions (Fig. 1G). A final example is turtle no. 238, which has notches at the 8, 9, 10, 11, and 12 positions (Fig. 1J). For numbers greater than 238, the 1-238 series may be repeated by coding with additional marks on the plastron or by toe clipping. For example, a notch in the ante-

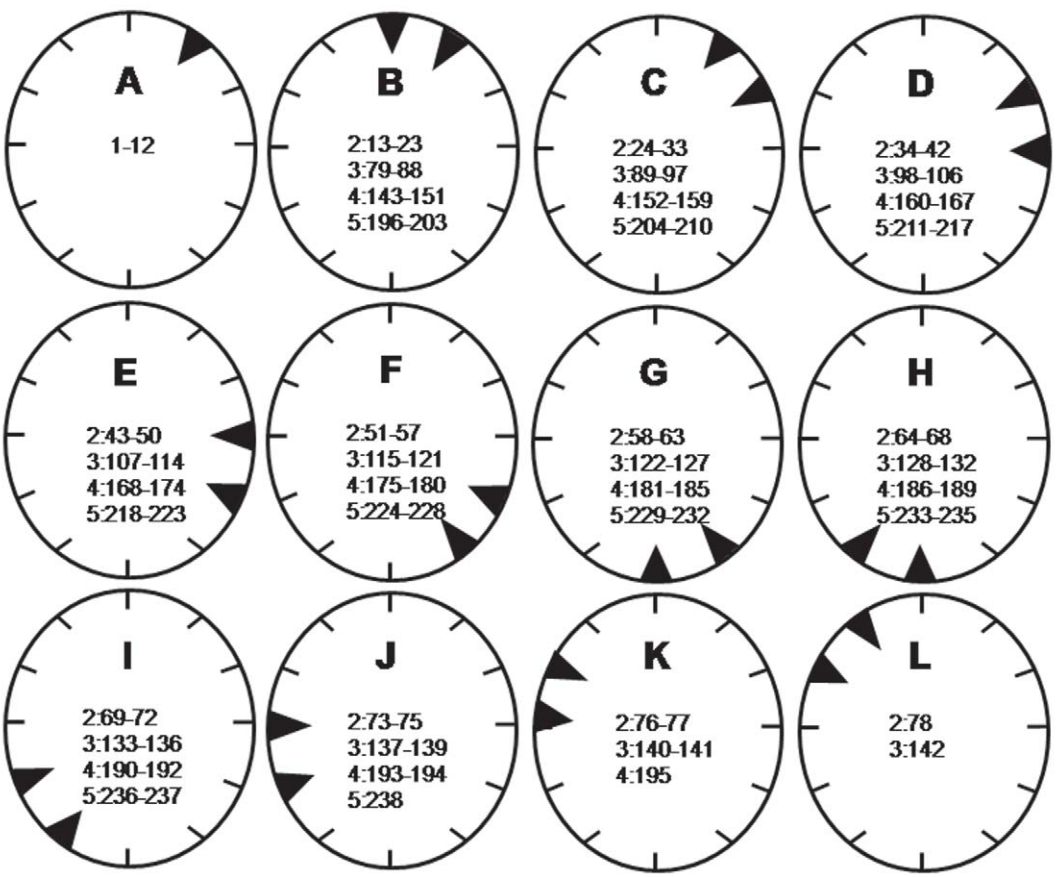

FIG. 1. Schematic of the proposed marking system for softshell turtles. Dark triangles represent notches in the carapacial margin corresponding to the hours of a 12 h clock. The first notch represents the starting position for numbering sequences in B (position 12) through L (position 10) for a two notch sequence. Numbers separated by a colon represent the number of notches to be cut and the range of turtle nos. that can be assigned from the starting position.

rior left quadrant of the plastron codes for turtle nos. 239–476, a notch in the anterior right quadrant codes for nos. 477–714, and notches in both the anterior left and right quadrants code for nos. 715–952. Using the 1–238 notching series and various combinations of just 1–2 notches in the four plastral quadrants would permit marking more than 2500 turtles.

Turtles unambiguously identified after extended periods of time between captures (Plummer and Mills, *in press*) demonstrate the long-term persistence of some marks. For example, 12 adult *A. spinifera* initially marked in 1994–95 were clearly identified 10–13 years later in 2005–07. In addition, five juvenile male *A. spinifera* initially marked at 30–60 mm plastron length (PL) were identified as adults 5–6 years later at 90–100 mm PL and 15 juvenile female *A. spinifera* initially marked at 30–60 mm PL were identified, some as adults, 7–13 years later at 140–215 mm PL. Whether marks on some individuals heal sufficiently to prevent identification is unknown; however, natural processes may occasionally alter marks. For example, the posterior most carapacial edge of adult males, which includes notching positions 5–7, is particularly susceptible to disfigurement resulting from aggressive intraspecific behavior (Doody and Tamplin 1992; Plummer 1977b). Growth from a small juvenile to a large adult may obscure marks such that periodic remarking is needed. Validation studies are needed to quantify the proportion of turtles that possibly "lose" their marks.

Several investigators have used shell marking in softshell mark-recapture studies (Breckenridge 1955; Doody and Tamplin 1992; Fitch and Plummer 1975; Graham and Graham 1997; Plummer 1977a; Plummer and Mills, *in press*); however, none described their marking methods in sufficient detail to be used by others. Thus, a systematic shell marking system designed specifically for the unique problems presented by marking large numbers of softshells for long-term studies is not available. The superiority of the system described herein may be open to question; however, its utility has been clearly demonstrated in population studies of two softshell species (Plummer 1979a; Plummer and Mills, *in press*). Whether the system would be suitable for other trionychid species is unknown. Various tagging techniques, such as PIT-tagging, offer advantages to shell marking and have been used on softshells (Galois et al. 2002), but they also have their own limitations (Gibbons and Andrews 2004).

Acknowledgments.—I thank Henry Fitch for challenging me in 1972 to devise a reliable marking system for softshells and Hunter Valls for reading the manuscript. The Arkansas Game and Fish Commission provided scientific collecting permits. This research was approved by the Harding University Animal Care Committee and was conducted following generally accepted guidelines for field research for reptiles (Anonymous 1987).

AMPHIBIAN CHYTRIDIOMYCOSIS GEOGRAPHIC DISTRIBUTION

This section offers a timely outlet for streamlined presentation of research exploring the distribution and prevalence of the amphibian chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*). *Bd* is an emerging infectious disease linked to mass mortality of amphibians worldwide, yet *Bd* detections in amphibians with no symptoms also are known in many areas. To aid in our understanding of the scope of this issue, we encourage submission of studies on *Bd* geographic distribution, including research on individual species or groups of species, wild or captive animals, native or non-native species, live animals or museum specimens, environmental samples, and findings with no *Bd* detections. We ask authors to: 1) restrict the Introduction of their paper to a **maximum** of two paragraphs to highlight the context of their study; 2) briefly include both field and laboratory Methods; 3) present Results in a Table, although a map also might be very useful, and limited text; and 4) have a short discussion of a **maximum** of three paragraphs to touch upon key findings. Please consider including the following information in submissions: coordinates and description of sampling areas (or please note if locations are extremely sensitive to reveal, and provide general area instead); positive and negative results; disposition of voucher specimens; date of specimen collec-

tion; name of collaborative laboratory or researcher conducting histological sections or PCR analyses; and names of cooperative land owners or land management agencies. We aim to expedite the review and publication process! Please e-mail submissions directly to Associate Editor, Dr. Dede Olson: dedeolson@fs.fed.us.

The Northern Leopard Frog, *Rana pipiens*, is wide-ranging across North America and commonly harvested for research and teaching (Gibbs et al. 1971; Moriarty 1998). *Rana pipiens* were harvested on the order of 100,000 specimens per year in the early 1980s in Quebec (Gilbert et al. 1994) and 100,000 pounds per year in the early 1970s in Minnesota (Moriarty 1998). Carey et al. (1999) suggested that population declines observed in this species in the late 1960s or early 1970s in some areas (Gibbs et al. 1971; Rorabaugh 2005) may have been caused by the emergence of chytridiomycosis, a disease caused by infection with the fungus *Batrachochytrium dendrobatidis* (*Bd*). A histological survey of *Bd* infections in *R. pipiens* collected in Quebec province of Canada between 1960 and 2001 revealed a prevalence of 10–20% (Ouellet et al. 2004). Because of their widespread commercial use and transport, we sampled several populations of this species to test for the potential of adult *R. pipiens* to act as a reservoir for *Bd* that could potentially facilitate the spread of disease.

Rana pipiens from Minnesota and Vermont were obtained from commercial suppliers (Table 1) and sampled by swabbing 10 times on each of ventral surface, thighs, and feet upon receipt at Vanderbilt University or after several months in the laboratory. Frogs arrived in boxes with damp sphagnum moss and were in contact with one another. Frogs were then housed in groups of 4–5 in polypropylene (opaque) plastic tanks with Plexiglas® covers (45.7 × 25.4 × 20.3 cm), sterilized with bleach before use, and tilted to one side to allow access to both water and the dry bottom of the container. In addition, *R. pipiens* were sampled in the field at a site near Plainwell, Michigan (42°19'26.7"N, 85°47'01.2"W). At the field site, individuals of six other species were sampled concurrently. Diagnosis of infection status, including the number of zoospore equivalents per swab, was performed at the Australian Animal Health Laboratory, CSIRO, Geelong, Victoria, Australia. All samples were analyzed in triplicate by Taqman real-time PCR assay according to Boyle et al. (2004). Sampling was different to that described by Hyatt et al. (2007) for groups containing multiple tadpoles or juveniles. Animals were rinsed in 50 ml HPLC-grade water for 15 min and the solution absorbed onto swabs as described by Boyle et al. (2004), perhaps underestimating infection loads.

We found that *R. pipiens* obtained from Minnesota and Vermont by two commercial suppliers were positive for *Bd*, indicating infection, but clinical signs of disease were absent. It is unknown whether the frogs became infected in the wild or after collection by suppliers. In general, infection intensity was low, typically ranging from 0 to 651 zoospore equivalents. A swab from one frog contained 90,599 zoospore equivalents. Although some animals died in captivity, there were no significant die-offs observed after housing frogs in the laboratory for several years, indicating that some *R. pipiens* may have resistance to chytridiomycosis. All 55 individuals and seven species sampled in the field in Michigan in 2004 were negative for *Bd*, indicating infection prevalence at the site between 0 and 6.49% with 95% confidence. The data imply that the Michigan population was probably not infected in the field. After exposure to water housing *R. pipiens* from commercial suppliers, at least one and up to four of six frogs collected from Michigan developed low-level *Bd* infections (Table 1).

These results suggest that *R. pipiens* can function as a reservoir or carrier species for *Bd*. This places *R. pipiens* in a category with other wide-ranging and introduced species used for food, fish bait, research, teaching, and pets (Fisher and Garner 2007). Current regulations do not require amphibian suppliers or breeders to deliver uninfected frogs or to check infection status. However, unless frogs escape or are released into new habitats, or their waste water is not treated, they do not necessarily put susceptible amphibians at risk. Unfortunately, disease emergence caused by introduced species that are *Bd* reservoirs is increasingly detected (Fisher and Garner 2007), for example in Britain (Cunningham et al. 2005) and Uruguay (Mazzoni et al. 2003). We recommend increased monitoring and stricter biosecurity to prevent the spread of chytridiomycosis. The overall health of amphibians obtained from commercial suppliers has improved since the report by Gibbs et al. (1971), and more rigorous distribution procedures will surely benefit research and conservation.

It seems unlikely that all populations of *R. pipiens* carry *Bd*. Therefore, measures should be taken to limit human-mediated exposure to the pathogen. Populations that already carry *Bd* may still be at risk. Different strains of *Bd* may differ in pathogenicity (Berger et al. 2005; Retallick et al. 2007). Hence, exposure of susceptible amphibians to new strains of *Bd* carried by *R. pipiens* and other reservoir species may continue to threaten populations with disease.

Of interest for conservation management, population level variation in susceptibility may exist, and this awaits exposure experiments and immune defense characterization of different populations. Since carrier species are expected to survive *Bd* exposure, susceptible controls may be used in exposure experiments as in Daszak et al. (2004).

This study was not extensive and is comprised of information

TABLE 1. Amphibians sampled for diagnosis of infection with *Batrachochytrium dendrobatidis*. Frogs obtained by commercial suppliers were sampled in the laboratory at Vanderbilt University. Samples that returned a low number of zoospore equivalents in only one well* or two wells** (from a total of three) were defined as "indeterminate."

accumulated while undertaking other studies. The data, however, are important because in addition to identifying *R. pipiens* as a carrier of *Bd*, they highlight the infectivity of *Bd* and the requirement for stringent biosecurity.

Acknowledgments.—We thank Jason Woodhams and Lawrence Woodhams for help with field collections, swamp property owners for access to field sites, and Louise Woodhams for hospitality. Batrachochytrium dendrobatidis in Wood Frogs (*Rana sylvatica*) from Three National Wildlife Refuges in Alaska, USA

MARI K. REEVES

U.S. Fish and Wildlife Service, Anchorage Fish and Wildlife Field Office
605 W. 4th Avenue, Room G-61, Anchorage, Alaska 99501, USA
e-mail: Mari_Reeves@fws.gov

Batrachochytrium dendrobatidis (*Bd*) is a fungal pathogen implicated in recent amphibian declines (Pounds et al. 2006). It was first documented in Alaska, USA, in 2002, in a single dead subadult Wood Frog (*Rana sylvatica*) in the Kenai National Wildlife Refuge (Reeves and Green 2006). Since then, there have only been two other studies of *Bd* in Alaska. In one, *Bd* was found in Boreal Toads (*Bufo boreas*) and Red-legged Frogs (*Rana aurora*) in western Canada and southeast Alaska (Adams et al. 2007). In the other, *Bd* was not found in wood frogs in Denali National Park (Chestnut et al. 2008). *Bd* distribution in other parts of Alaska is unknown. In summer of 2006, we sampled adult Wood Frogs from three Alaskan National Wildlife Refuges to screen them for *Bd*.

Methods.—Wood Frogs from the Innoko, Kenai, and Tetlin refuges were sampled (Fig. 1). From these refuges, we tested 48 opportunistically-encountered adult frogs from 29 breeding ponds between 11 May and 21 July 2006 (Table 1). At Kenai, four ponds were road-accessible and six were in remote areas, 1–10 km from any road (Fig. 1). All ponds at Innoko (N = 9) and Tetlin (N = 10) were in remote areas, 35–125 km from any road. All animals were alive when sampled and appeared healthy. Frogs were swabbed

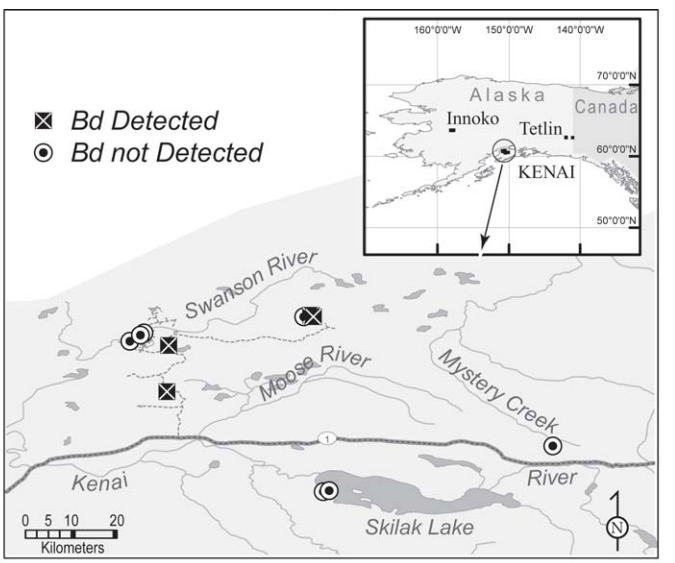

Fig. 1. Wood Frog (*Rana sylvatica*) *Bd* sampling locations in Alaska, USA, and Kenai Refuge sampling ponds and *Bd* detection locations. Dashed lines are gravel roads.

TABLE 1. Surveys for *Batrachochytrium dendrobatidis* (*Bd*) in Wood Frogs (*Rana sylvatica*) in three wildlife refuges in Alaska, USA. Prevalence indicates: number of frogs with *Bd* detected/total number of frogs sampled.

30–35 times on the pelvic patch, inner thighs, and between toes with sterile, foam-tipped swabs (REF 25-1506 1PF: Puritan, Guilford ME). Swab tips were then placed in individual 1.5 ml microfuge tubes in reagent-grade ethanol and stored at room temperature until analysis. Samples were sent in late August 2006 to Pisces Molecular (J. Wood, Boulder, Colorado, USA) for analysis by polymerase chain reaction (Annis et al. 2004). Clean nitrile gloves were worn when handling each frog, and field equipment was decontaminated with 5% bleach solution between ponds. Pond coordinates were recorded with hand-held Garmin III GPS units and referenced to datum, WGS84.

Results.—Bd was detected in the Kenai refuge, but not in the Tetlin or Innoko refuges. In Kenai, *Bd* was found in one of four road-accessible ponds and in two of six remote ponds; in the three ponds where *Bd* was found, all sampled frogs tested positive (Table 1). All of the *Bd*-positive ponds were near the Swan Lake recreational canoe route or the gravel road used to access it (Fig. 1). One of the *Bd*-positive ponds was directly adjacent to the road, and the other two ponds were in a wilderness area within 3 km of the road and within 1 km of the canoe trails.

Discussion.—Wood Frogs are the only amphibian common in southcentral and interior Alaska (Wright and Wright 1995). In these regions, *Bd* has been found only on the Kenai refuge, in limited locations (1 pond in 2002 and 3 ponds in 2006). The dead Wood Frog found in 2002 (Reeves and Green 2006) was in a different pond along the same access road as our 2006 *Bd* detections; all positive detections in the Kenai refuge thus have been along this recreational access corridor. Of the four remote ponds that tested negative for *Bd* in 2006, two are in areas where human visitation is rare or nonexistent (access requires a motor boat and then a walk through trail-less forest), one is in a wilderness area near an established hiking trail, and one is near the recreational canoe route and the two ponds that tested positive. Amphibian researchers have visited all the remote ponds repeatedly since 2004, using hygiene protocols described above. The three road-accessible ponds that tested negative for *Bd* are on an operating oil field, where the public is not allowed. The oil field ponds have been visited by amphibian researchers since 2000, and access by other people is limited to oil field workers and other (non-amphibian) researchers. It is unlikely these other users enter the wetlands sampled in this study, although the roads pass within 100 m of each pond. The ponds in the Innoko and Tetlin refuges are all remote, requiring a combination of planes and watercraft to access, and it is unlikely that any people other than amphibian researchers enter the ponds sampled for this study. Although sample size is limited, the results from this study suggest *Bd* is not ubiquitous in southcentral and interior Alaska. More systematic research is needed on the distribution and abundance of *Bd* in Alaskan refuges, especially as it relates to recreational use.

Acknowledgments.—Funding was provided by the U.S. Fish and Wildlife Service, Division of Environmental Quality. The following refuge staff provided logistical support: S. Kovach, J. Morton, J. Hall, C. Caldes, R. West, and B. Johnson. Insightful comments on the manuscript were given by M. Nemeth, D. Olson, and an anonymous reviewer. Field assistants were M. Purdue, S. Jensen, P. Jensen, N. Maxon, T. Hahka, and C. Wall. We thank K. Christiansen with the U.S. Forest Service, Pacific Northwest Research Station, Corvallis, Oregon, for creating Fig. 1. All animals in this study were treated humanely in accordance with institutional Animal Care guidelines, and required federal and state permits were obtained.

Amphibian chytrid fungus (*Batrachochytrium dendrobatidis*) infection has been well-studied in Australia and the New World, where species seem to be especially susceptible to infection in montane, stream habitats (e.g., Carnaval et al. 2006; Hero and Morrison 2004; Lips et al. 2004; McDonald et al. 2005). The destructive fungus also has been associated with frog die-offs and mortality in similar habitats in East and South Africa (e.g., Channing et al. 2006; Hopkins and Channing 2003; Smith et al. 2007), and it is likely that the fungus is killing frogs in other highland regions throughout Africa. If present, the fungus could be potentially catastrophic in Central Africa where the species richness, endemism, and numbers of threatened amphibians are among the highest in continental Africa (Burgess et al. 2004; IUCN et al. 2006). Moreover, the amphibians of Central Africa are poorly surveyed or unknown in many areas (Broadley and Cotterill 2004; Channing and Howell 2006; Laurent 1983; Plumptre et al. 2003; Schmidt and Noble 1919), and thus, infections could wipe out species before they are identified by science. Remarkably, no published study has examined amphibians in Central Africa for the presence of chytrid fungus.

We (EG, CK, and MA) conducted a preliminary survey of the herpetofauna at sites in and near Kahuzi Biega National Park (a UNESCO World Heritage Site in Danger), South Kivu Province, Democratic Republic of Congo between 14 August and 2 September 2007. Habitats ranged from high-elevation bamboo forest to lowland rainforest, and although the timing of our collecting corresponded to the dry season for the eastern Congo highlands (Chapin 1932) we observed some rainfall almost daily. Amphibians were collected by hand, euthanized via cutaneous contact with Orajel®, and preserved in 10% formalin solution; after a 24 h rinse in water, specimens were transferred to 75% ethanol and 1–4 mm toe clippings of 24 selected specimens (Table 1) were prepared for histological examination. Tissues were dehydrated in graded concentrations of ethanol and then xylene, paraffin-embedded, sectioned at 4 microns and stained with hematoxylin and eosin. To avoid delays from cataloging backlogs, field numbers are provided for voucher specimens, but these specimens will be deposited in an American natural history museum collection in the future. Abbreviations are as follows: EBG = Eli Greenbaum field series; SVL = snout–vent length.

Two of 24 specimens (EBG 1087 and EBG 1307) showed evidence of chytridiomycosis. The former specimen is a subadult *Hyperolius kivuensis* (19.7 mm SVL; adult size 22–39 mm according to Schiøtz 1999) with no evidence of lesions. A juvenile *H. kuligae* (EBG 1307; 10.1 mm SVL; adult size 20–31 mm according to Schiøtz 1999) has multiple small, white lesions on the venter of the hind limbs and abdomen. Infections were characterized by thickening of the superficial keratinized layers of the epidermis due to the presence of smooth-walled sporangia of *Batrachochytrium* that ranged in diameter from 10–25 microns. Most sporangia were empty, but several contained five to ten zoospores (Figs. 1A, B). No hyphae were present and there was no inflammatory cell response in the deeper layers of the epidermis and dermis. Twenty-two additional specimens representing 17 additional anuran species were negative for chytrid infection (Table 1).

To the best of our knowledge, the chytrid infections reported herein are the first positive results for any amphibian in Central Africa, where the fungus is present in both lowland (primary rainforest) and highland (secondary montane forest) habitats. Both infected individuals were collected in (EBG 1087) or near (EBG 1307) streams in close proximity to (< 1 km) human habitations and agricultural fields. The subadult and juvenile ages of the infected frogs are consistent with the high rate of infection and mortality reported for postmetamorphic frogs in Africa and Australia (Berger et al. 1999; Smith et al. 2007).

Weldon et al. (2004) hypothesized that *Batrachochytrium*

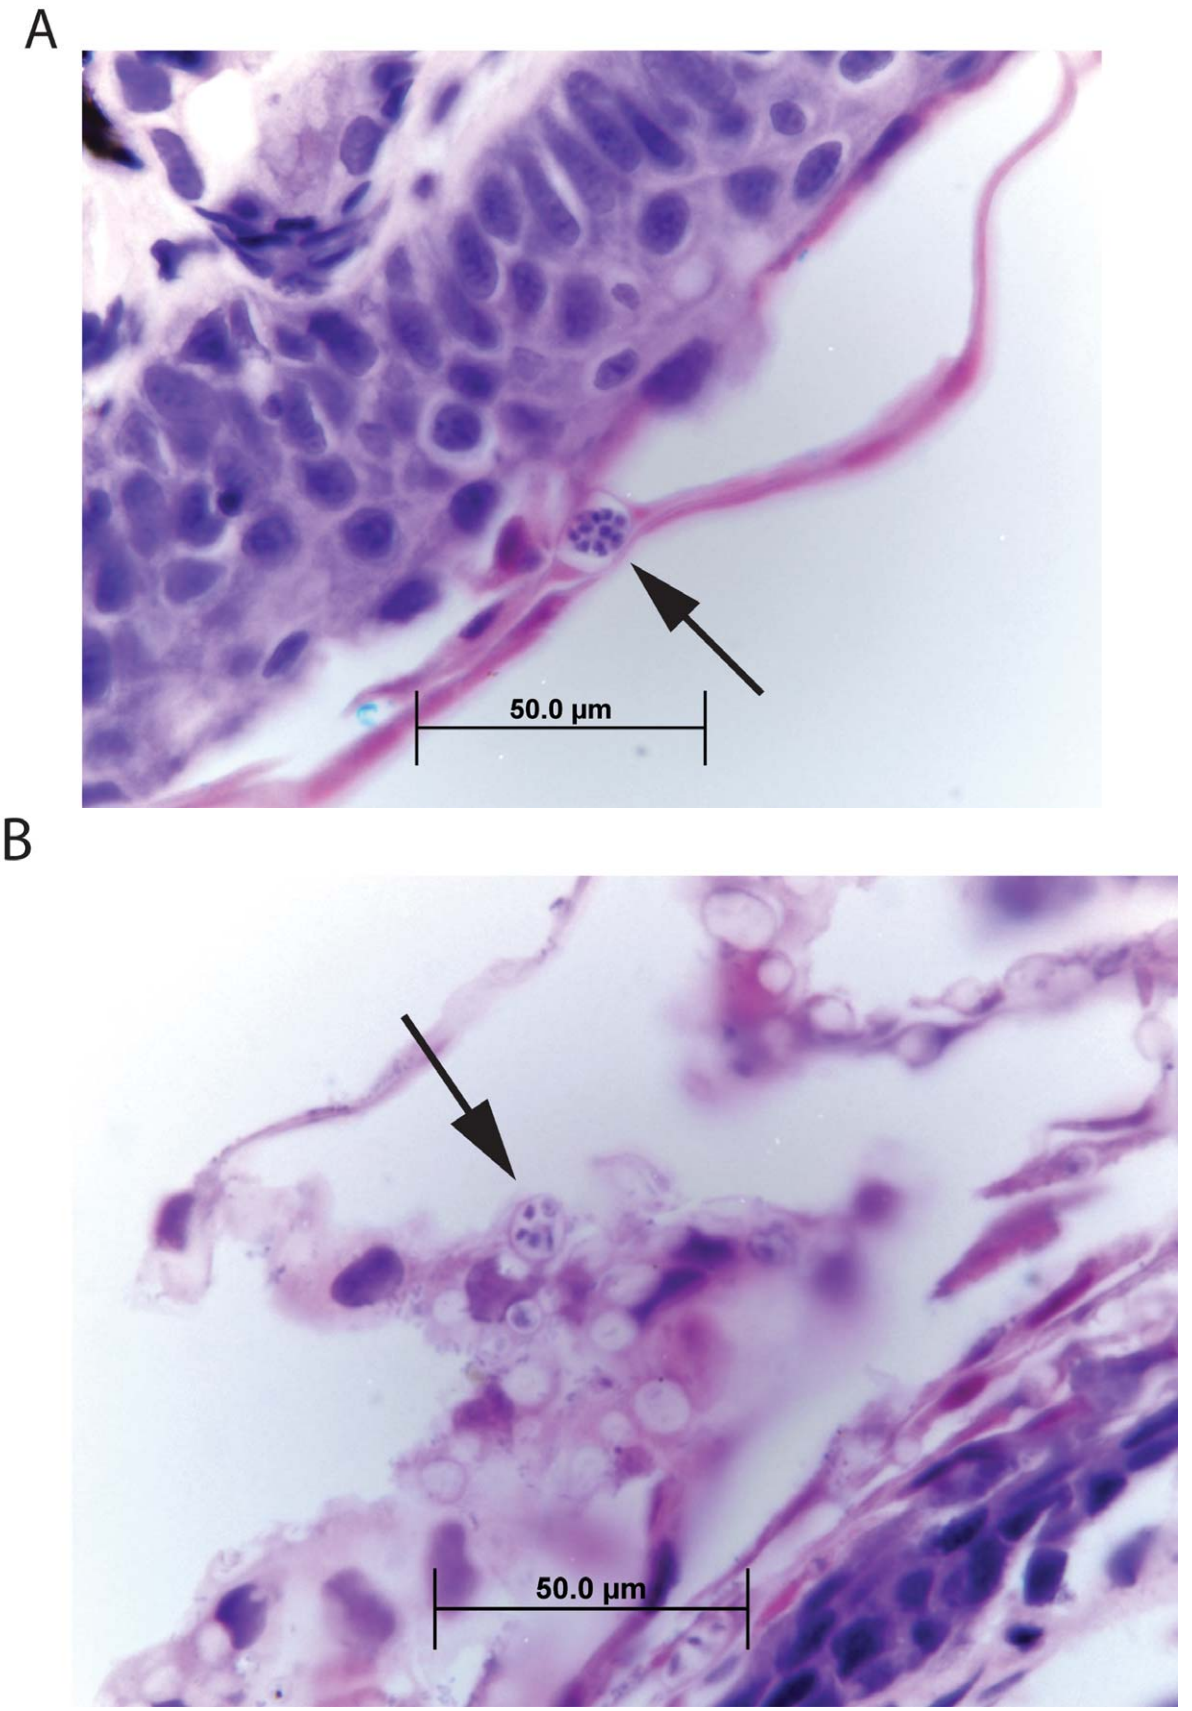

FIG. 1. Chytridiomycosis was detected in two frogs from the eastern Democratic Republic of Congo in Summer, 2007. (A) Sporangia (arrow) containing 10 zoospores from the toe of a subadult *Hyperolius kivuensis* (EBG 1087) from Tshivanga; (B) skin from the toe of a juvenile *Hyperolius kuligae* (EBG 1307) from Irangi. The superficial keratinzed layer of epidermis is markedly thickened from numerous round-to-oval sporangia of *Batrachochytrium dendrobatidis*. Most of the sporangia are empty, but one contains five zoospores (arrow).

TABLE 1. List of amphibian species tested for chytrid infection, including locality information. EBG = Eli Greenbaum field series. All localities are in South Kivu Province, Democratic Republic of Congo. Coordinates are from the WGS 84 datum.

Field Number	Species	Locality	Date of Collection	Habitat	Chytrid Infection
EBG 1316	*Afrixalus laevis*	Forest near Irangi, -1.8873055, 28.4495, 820 m	28 Aug 07	Primary rainforest	Negative
EBG 1336	*Afrixalus osorioi*	Irangi, -1.8743611, 28.4523611, 806 m	29 Aug 07	Secondary rainforest	Negative
EBG 1331	*Afrixalus quadrivittatus*	Irangi, -1.8743611, 28.4523611, 806 m	29 Aug 07	Secondary rainforest	Negative
EBG 1178	*Amietophrynus* sp.	Lwiro, -2.2383611, 28.8051944, 1750 m	18 Aug 07	Agricultural pond in cleared montane forest	Negative
EBG 1255	*Arthroleptis* cf. *adolfifriederici*	Mugaba, -2.2750278, 28.6631111, 2333 m	26 Aug 07	Bamboo forest	Negative
EBG 1111	*Hyperolius castaneus*	Mbayo, -2.2545833, 28.7680556, 2146 m	15 Aug 07	Stream near edge of montane forest	Negative
EBG 1253	*Hyperolius castaneus*	Mugaba, -2.2750278, 28.6631111, 2298 m	25 Aug 07	Montane forest	Negative
EBG 1372	*Hyperolius cinnamomeoventris*	Catena near Irangi, -1.8655, 28.4526944, 805 m	30 Aug 07	Primary rainforest	Negative
EBG 1087	*Hyperolius kivuensis*	Maziba village, near Tshivanga, -2.3128056, 28.7551944, 2200 m	14 Aug 07	Stream near edge of montane forest	Positive
EBG 1160	*Hyperolius kivuensis*	Lwiro, -2.2383611, 28.8051944, 1750 m	18 Aug 07	Agricultural pond in cleared montane forest	Negative
EBG 1307	*Hyperolius kuligae*	Forest near Irangi, -1.8873056, 28.4495, 820 m	28 Aug 07	Vegetation 2 m above a stream in primary rainforest	Positive
EBG 1110	*Hyperolius nasutus*	Mbayo, -2.2545833, 28.7680556, 2146 m	15 Aug 07	Stream near edge of montane forest	Negative
EBG 1226	*Hyperolius nasutus*	Nyakasaz Swamp near Lwiro, -2.2278889, 28.7793333, 1991 m	23 Aug 07	Swamp near secondary montane forest	Negative
EBG 1120	*Hyperolius* sp.	Mbayo, -2.2783611, 28.77175, 2146 m	15 Aug 07	Flooded reeds adjacent to montane forest	Negative
EBG 1344	*Leptopelis christyi*	Irangi, -1.8743611, 28.4523611, 806 m	29 Aug 07	Secondary rainforest	Negative
EBG 1116	*Leptopelis* cf. *kivuensis*	Mbayo, -2.2783611, 28.77175, 2146 m	15 Aug 07	Flooded reeds adjacent to montane forest	Negative
EBG 1282	*Leptopelis* cf. *kivuensis*	Mugaba, -2.2671389, 28.6455, 2267 m	26 Aug 07	Montane forest	Negative
EBG 1127	*Ptychadena* cf. *chrysogaster*	Kayumaga stream near Mbayo, -2.2663056, 28.7838056, 1943 m	17 Aug 07	Agricultural stream in cleared montane forest	Negative
EBG 1213	*Ptychadena* cf. *chrysogaster*	vicinity of Lwiro, -2.2333333, 28.8, 1750 m	23 Aug 07	Agricultural pond in cleared montane forest	Negative
EBG 1292	*Ptychadena mascareniensis*	Irangi, -1.8746667, 28.4523889, 793 m	27 Aug 07	Secondary rainforest edge puddles	Negative
EBG 1142	*Schoutedenella* cf. *schubotzi*	Mbayo, -2.2590278, 28.7683056, 2156 m	17 Aug 07	Road in cleared montane forest	Negative
EBG 1294	*Xenopus pygmaeus*	Irangi, -1.8743611, 28.4523611, 806 m	27 Aug 07	Roadside ditch near secondary rainforest	Negative
EBG 1169	*Xenopus victorianus*	Lwiro, -2.2383611, 28.8051944, 1750 m	18 Aug 07	Agricultural pond in cleared montane forest	Negative
EBG 1105	*Xenopus wittei*	Mbayo, -2.2783611, 28.77175, 2150 m	15 Aug 07	Agricultural pond near secondary montane forest	Negative

dendrobatidis originated in Southern Africa and spread to other regions of the world through commercial frog trade. Based on this premise, Smith et al. (2007:163) suggested that the relative rarity of amphibian die-offs associated with *B. dendrobatidis* in southern Africa reflects regional differences either in the pathogenicity or the host response to chytrid infection. Because we observed large, reproducing populations of *Hyperolius kivuensis* and *H. kuligae* in several localities in and near Kahuzi Biega, it is possible that chytrid infections in these species are not causing significant mortality rates.

Our results are likely an underestimate of the true incidence of chytrid infection in Kahuzi Biega for four reasons: 1) to minimize destructive sampling, we examined toe clippings from only one specimen per species in a given locality; 2) we sampled a small portion of the epidermis, and sampling from more areas of the body could have identified additional, positive infections; 3) we did not want to engage in destructive sampling of several unique specimens from species that are rare (e.g., *Arthroleptis* sp., *Hyperolius ocellatus*, *Leptopelis modestus*) or potentially new; and 4) because of recent warfare and ongoing rebel militia activity (Afoaku 2004; Barnes and Lahm 1997; Edgerton 2002; Hart and Liengola 2005), it was not possible to sample amphibians in many unique habitats in the park (Fischer 1996). Further testing is needed for additional species and localities throughout the Albertine Rift to assess potential threats to scores of amphibians (including several monotypic genera) with limited distributions in the highlands (IUCN et al. 2006; Laurent 1983; Plumptre et al. 2003). The presence of the fungus in lowland habitats of eastern Congo also underscores the need for testing in multiple elevations and habitats to improve understanding of the distribution and niche requirements of the fungus.

Acknowledgments.—We thank Ben Evans for assistance with *Xenopus* frog identification and Patrick Kraus for preparing the histology specimens. We appreciate our field companions Maurice L. Mutwa and Celestin B. Chimanuka, and Baluku Bajope of CRSN for project support. Kevin G. Smith and one anonymous reviewer provided helpful comments on an earlier version of the manuscript. This project was supported by an IUCN/SSC Amphibian Specialist Group Seed Grant to the senior author. Additional thanks to Aaron Bauer and Russell Gardner for project support and research funds from the Department of Biology at Villanova University.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations in the field, with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance.

Electronic submission of manuscripts is requested (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Figures can be submitted electronically as JPG files, although higher resolution TIFF or PDF files will be requested for publication. Please DO NOT send graphic files as imbedded figures within a text file. Additional information concerning preparation and submission of graphics files is available on the SSAR web site at: http://www.ssarherps.org/HRinfo.html. Manuscripts should be sent to the appropriate section editor: **Marc P. Hayes** (crocodilians, lizards, and *Sphenodon*; mhayesrana@aol.com); **Charles W. Painter** (amphibians; charles.painter@state.nm.us); **Andrew T. Holycross** (snakes; holycross@asu.edu); and **James Harding** (turtles; hardingj@pilot.msu.edu).

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico.* SSAR Herpetol. Circ. 37:1–84, available from SSAR Publications Secretary, ssar@herplit.com; for Mexico as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish.* Herpetol. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA – SALAMANDERS

AMBYSTOMA CALIFORNIENSE (California Tiger Salamander). **PREDATION**. *Ambystoma californiense* is an endemic species listed as threatened by the Department of the Interior (U.S. Fish Wild. Serv. 2004. Fed. Reg. 69:47212–47248) and as a species of special concern by the State of California (Jennings 2004. California Fish Game 90:161–213). Although many factors are stated for the decline of this salamander, wild pigs (*Sus scrofa*)—a game species first introduced into California in the 1920s—are suspected to eat juvenile and adult salamanders and also negatively impact salamander habitats (U.S. Fish Wild. Serv. 2003. Fed. Reg. 68:28648–28670). Here we report on the first documented incident of wild pigs negatively effecting *A. californiense* eggs.

On Blue Oak Ranch in Santa Clara County, California (USA), an early storm brought ca. 7.6 cm of rain between 7 and 9 Nov 2003, saturating the soil. The next storm delivered just over 2.5 cm of rain overnight on 14–15 Nov, causing Junction Pond (37.375556°N, 121.724444°W; elev. 599 m) to fill to a maximum depth of 33 cm in a basin ca. 4 m in diameter. On 20 Nov, we discovered 60 *A. californiense* eggs attached to the substrate of the pond, primarily on Dove Weed (*Eremocarpus setigerus*). No precipitation events occurred over the next 5 days. Humidity was quite low because of offshore winds, with high temperatures reaching almost 29°C and nighttime lows dipping to 2°C. As a result, the water level in Junction Pond dropped to ca. 15 cm, with the diameter of the pond basin shrinking to ca. 2 m. While checking on the *A. californiense* eggs on the morning of 25 Nov, we discovered that wild pigs had used the pond basin as a wallow, crushing most of the eggs and detaching the remainder from their substrates. Those that were not crushed, eaten, or buried in the mud were frozen in the thin ice that covered the surface of the small area of remaining water. Pigs continued to wallow in Junction Pond until rains filled it completely in mid-December.

GIBESON**, 36 San Marin Drive, Novato, California 94945, USA (e-mail: bdgibeson@comcast.net); and **MARK R. JENNINGS**, Rana Resources, PO Box 2185, Davis, California 95617 USA, and Research Associate, Department of Herpetology, California Academy of Sciences, 875 Howard Street, San Francisco, California 94103, USA (e-mail: RanaResources@aol.com).

ANURA – FROGS

ARGENTEOHYLA SIEMERSI PEDERSENI (Rana Tractor or Rana de Pedersen). **REPRODUCTION**. *Argenteohyla siemersi* is an uncommon Neotropical hylid frog listed as Endangered by IUCN (2006. Conservation International and NatureServe. Global Amphibians Assessment. http://www.globalamphibians.org. Accessed 01 Mar 2007). The main threat is habitat destruction caused by fires to expand/maintain pastures and pine forestry plantations. *Argenteohyla siemersi pederseni* occurs in northwest Corrientes Province (Argentina), inhabiting the leaf axils of terrestrial *Aechmae* bromeliads in gallery forests along main river systems. Its population appears to be stable (IUCN 2006, *op. cit*).

Reproduction in *A. siemersi pederseni* takes place in temporary pools close to bromeliads. The larva was described by Céspedez (2000. Bol. Asoc. Herpetol. Esp. 11:75–80), who counted 1020 ova (1–1.5 mm diam) in a gravid female. Barrio (1969. Physis 26[71]:225–228) reported diurnal choruses of *A s. siemersi*, from noon to late afternoon.

Here we provide data on clutch size and characteristics of the reproductive behavior in *Argenteohyla siemersi pederseni*. On 28 Sept 2006, at 2330 h after heavy rains (air temp 14.5°C; water temp 17.5°C; humidity 74%), we observed several calling males and two pairs in axillary amplexus in a semi-permanent pond in the Reserva Provincial Iberá (28.68°S, 57.43°W, WGS 84; elev. 65 m), near Colonia Carlos Pellegrini, Corrientes, Argentina. We did not observe bromeliads near the pond. The males had paired vocal sacs and called from the water, floating in open spaces, or near of the edge of the pond among aquatic vegetation (Fig. 1). The vocalization occurred from 1800 h to past midnight in choruses of 3–4 males.

The next day a clutch with ca. 2464 eggs was found in the same pond. The eggs were dark at the animal pole and creamy yellow at the vegetal pole. Mean diameter was 1.73 mm (SD = 0.86, range 1.5–1.9 mm, N = 109). They were laid in gelatinous ribbons floating at the surface of the water or among aquatic vegetation (Fig. 2). Other species reproducing in the same pond were *Scinax squalirostris*, *Chaunus fernandezae*, *Pseudopaludicola falcipes*, and *Elachistocleis bicolor*.

FIG. 1. Calling male *Argenteohyla siemersi pederseni*. Photograph by Víctor Zaracho.

FIG. 2. Egg clutch of *Argenteohyla siemersi pederseni*. Photograph by Víctor Zaracho.

This is the first description of an egg clutch of the genus *Argenteohyla*.

Libertad 5470, (3400) Corrientes, Argentina (e-mail: victorzaracho@yahoo.com.ar).

BUFO AMERICANUS (American Toad). **REPRODUCTION**. Herein I report an instance of prolonged amplectant behavior with an inanimate object in the bufonid *Bufo americanus*. On 22 April 2007 at ca. 2200 h, I visited South Run District Park (Fairfax Co., Virginia, USA) and observed a male *B. americanus* in amplexus with a tennis ball (Fig. 1). The individual manipulated the tennis ball for ca. 2 min until he finally released his misguided embrace. Although a breeding chorus was well established, the sex ratios appeared to be skewed with males outnumbering females 30:1 in this particular vernal pool. Given the importance of release and advertisement calls for mate recognition in *B. americanus* (Leary 2001. Can. J. Zool. 79[9]:1577–1585), it is not surprising that this instance of amplectant behavior was prolonged. While some bufonid studies have incorporated mating interactions with inanimate objects (Hinsche 1926. Zeitschr. Vergl. Physiol. 4:564–606) few have given an example of this behavior in a natural setting. Despite this, it is well known among field workers that breeding male *B. americanus* will readily grasp objects placed between their front limbs (e.g., worker's fingers) (Tupper, pers. comm.). As suggested by Höbel (2005. Herpetol. Rev. 36:55–56; 2005. Herpetol. Rev. 36:439–440), it is likely that male anurans are more prone to mating mistakes when, as in this scenario, there is high competition for conspecific females.

FIG. 1. Male *Bufo americanus* in amplexus with a tennis ball, found in northern Virginia, USA.

BUFO PUNCTATUS (Red-spotted Toad). **PREDATION**. Adult *Bufo punctatus* are predated by some vertebrates, mainly aquatic snakes but also, turtles (Stone et al. 2005. Herpetol. Rev. 36:312), and birds and mammals (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts, 533 pp.); tadpoles are predated by gartersnakes and aquatic beetle larvae (Coleoptera) (Livo and Kondratieff 2000. Herpetol. Rev. 31:168–169). In Baja California Sur (BCS), adult *B. punctatus* are part of the diet of gartersnakes (Blázquez 1996. Herpetol. Rev. 27:83–84; Rodríguez-Robles and Galina-Tessaro 2006. Herpetol. Rev. 37:335. Herein, we report predation of an adult *B. punctatus* by the giant aquatic bug, *Lethocerus angustipes* (Heteroptera: Belostomatidae).

At 2138 h on 30 Aug 2006, we found an adult male (60.6 mm SVL, 17 g) *B. punctatus* held by the left hind limb by an adult female *L. angustipes* (60 mm TL). The pair was floating in a small temporary pond near Rancho El Álamo, northern BCS, México (27.108083°N, 112.927306°W), ambient air temperature was 27.1°C and water temperature was 29.4°C. The toad made erratic movements with its forelimbs, but the posterior part of its body seemed paralyzed by the toxins of the *L. angustipes* (Smith 1997. Cambridge University Press). After an hour of observation the toad stopped moving and died.

This observation confirms that *L. angustipes* are voracious predators in freshwater systems and, in addition to aquatic invertebrates and tadpoles (Kehr and Schnack 1991. Alytes 9[3]:61–69), can predate adult toads.

Bufo punctatus and *L. angustipes* were deposited in herpetological and entomological collection respectively, of the Centro de Investigaciones Biológicas del Noroeste (CIBNOR), La Paz, Baja California Sur, México. We thank to A. Cota for assistance with fieldwork and C. Palacios for assistance identifying *L. angustipes*.

Submitted by **VICTOR H. LUJA** (e-mail: lujastro@yahoo.com), **M. CARMEN BLÁZQUEZ**, and **RICARDO RODRÍGUEZ-ESTRELLA**, Centro de Investigaciones Biológicas del Noroeste (CIBNOR), Mar Bermejo #195 Colonia Playa Palo de Santa Rita, La Paz, Baja California Sur, 23090, México.

CRAUGASTOR TALAMANCAE (NCN). **REPRODUCTION AND NEST ATTENDANCE.** The genus *Craugastor* contains 116 species of poorly known tropical direct-developing frogs. While most of the species are characterized by small clutch size, large egg size, and attendance of terrestrial nests by one of the parents, descriptions of reproductive behavior are lacking for the majority of species (Townsend 1996. *In* Powell and Henderson [eds.], Contributions to West Indian Herpetology, a Tribute to Albert Schwartz, pp. 229–239. SSAR Conrib. Herpetol. Vol. 12. Ithaca, New York). Herein, we provide what we believe to be the first report of reproduction in the Central American frog *Craugastor talamancae*, including descriptions of the clutch, the nesting site, and attendance of the nest by the female parent.

On 31 Jan 2007 at ca. 1300 h, we encountered an adult *C. talamancae* with a clutch of 36 eggs in an old-growth lowland tropical wet forest at La Selva Biological Station, Heredia Province, Costa Rica (10.41°N, 84.00°W, ca. 60 m elev.). The nest was located on the ground, under leaf litter, and consisted of a round depression in the soil ca. 50 mm diameter and ca. 25 mm deep. The egg mass was ca. 40 × 30 mm, and ca. 15 mm high. The eggs were ca. 6 mm in diameter. The attending frog was first noted leaping from the vicinity the clutch. We determined the attending frog to be a female by comparison of the relative size of the tympanum to the eye (Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. Chicago Press. Chicago, Illinois. 934 pp.). The female measured 43.5 mm SUL and 7.75 g. Embryos were stages 5–7 (Townsend and Stewart 1985. Copeia 1985:423–436) because the yolk was cream white, eyes were prominent and darkly pigmented, pupils were clear, and embryos were pink with nascent hind limbs and a short tail, but no evident forelimbs. We collected five eggs from the clutch and kept them in a small container containing moist paper towels at ambient temperature.

FIG. 1. A female *Craugastor talamancae* perched upon a clutch of eggs in leaf litter at La Selva Biological Station, Costa Rica.

We checked the status of the nest in the field on 08 Feb 2007 at ca. 1300 h. At this time, the nest was intact, and the female was perched directly on top of the clutch of eggs. When we checked the nest on 14 Feb 2007 at ca. 1300 h there were no eggs in the nest cavity and the female was not present nearby. However, one egg was still present in the vicinity of the nest, ca 15 cm from the nest cavity, and appeared intact. On 20 Feb 2007, all five of the artificially incubated eggs hatched; the froglets measured 8.8, 8.8, 9.0, 9.0, and 9.2 mm SUL.

To our knowledge this is the first report of reproduction and nest attendance in *Craugastor talamancae*. Nest attendance is common in *Craugastor*, although some species lack this or other parental behavior. While we observed no active parental behavior (such as hydrating eggs or defending the nest from predators), we believe that the occurrence of the female perched upon the clutch containing eggs at such a late developmental stage, on two occasions, to be strong evidence of active nest attendance. Further, while we are unable to determine the development time for these eggs, we presume that hatching must occur significantly longer than 21 days after oviposition because we found these eggs at an intermediate developmental stage. Finally, because the eggs in the field disappeared before the eggs in the lab hatched, we presume that these eggs failed to hatch, likely due to nest predation.

FEJERVARYA LIMNOCHARIS (Indian Cricket Frog). **MORPHOLOGY.** In agriculture fields, amphibian populations are affected by chemical contaminants and managerial practices. Earlier reports have shown that exposure to these contaminants can result in expression of behavioral and morphological abnormalities and contribute to the decline of amphibian populations in agro ecosystems (Daniels 2003. Curr. Sci. 85:1415–1422). Similar incidences have been reported from various habitats of central Western Ghats (Gurushankara et al. 2007. Appl. Herpetol. 4:39–45). Ouellet (2000. *In* Sparling [ed.], Ecotoxicology of Amphibians and Reptiles, pp. 617–661) reported that abnormalities of amphibians in tropical habitats ranged between 0 and 2%. In the following report, we present information on abnormalities of adult *Fejervarya limnocharis* recorded in paddy fields of central Western Ghats. In these fields, regular application of pesticides (organochlorine and organophosphate, range 300–700 mL ha^{-1} per crop) and synthetic manures (nitrophosphate and potash, range 200–300 kg ha^{-1} per crop) is being practiced.

Fejervarya limnocharis is a common inhabitant of all agro ecosystems in central Western Ghats, where it breeds in the shallow water of paddy fields. A survey of *F. limnocharis* was made at ten different plots, each 2.5 ha, in paddy fields located (13.53°–1373°N and 75.63°–75.66°E), near the Bhadra River Dam in Karnataka State of India. Surveys were conducted during January–March 2007 after harvest. During these surveys 259 adult frogs (mean SVL 21.39 mm, SD 4.951 mm) were collected and visually examined for abnormalities following the field keys of Meteyer (2000. Biological Science Report USGS/BRD/BSR-2000-0005). Of the 259 individuals examined, 28 (10.8%) were abnormal. Abnormalities recorded were tumors with disfigured hind limb bones (39.29%), short-toe/ brachydactyly (35.71%), missing digit/Ectrodactyly (21%), and incomplete limb/Ectromelia (3.6%).

Becon et al. (2000. Appl. Herpetol. 3:39–65) observed 5% abnormality of frogs living in contaminated agro ecosystems of Asia, some parts of Europe, and America. Compared to these observations, the occurrence of 10.8% abnormality in our area is very high. Given that pesticides and chemical manures are added to every crop, the likelihood that contaminants cause abnormalities in *F. limnocharis* is high.

HYLARANA RANICEPS (White-lipped Frog). **PREDATION.** We relate herein an observation of the predation of a *Hylarana raniceps* metamorph by a spider. *H. raniceps* is a common species in the lowlands of Bornean dipterocarp forests. In March 2007, we observed a "fishing spider" of the species *Thalassius* cf. *albocinctus* (Doleschall, 1859) at a alluvial pond off Headhunters' Trail, near Camp 5 (04.139056°N, 114.899944°E), Gunung Mulu National Park, Sarawak, East Malaysia (Borneo), with a metamorph of *H. raniceps* as prey. The spider was sitting on a vertical trunk in the pond, about 20 cm above the pond surface and was grasping the right thigh of the metamorph (Fig. 1). The spider was disturbed by photography and ran down the trunk with the prey, entered into the water and actively dove to the bottom at about 1 m below surface. Shortly afterwards, it surfaced again and released the dead metamorph. *Thalassius albocinctus* is well known for fishing small sized fishes from the surface layer of standing or slow running waters.

FIG. 1. *Hylarana raniceps* metamorph captured by a "fishing spider" (Pisauridae: *Thalassius* cf. *albocinctus*), Gunung Mulu National Park, Malaysia.

At Gunung Mulu National Park, we frequently saw *T.* cf. *albocinctus* hunting on the surface of ponds with an abundance of breeding frogs and therefore we assume it to be a common amphibian predator. Toledo (2005 Herpetol. Rev. 36:395–400) reported that risk of invertebrate predation on amphibians is proportionately high during the breeding season and in recently metamorphosed frogs, compared to other life history stages, and we speculate that predation by fishing spiders might have an important impact on larval and metamorph survival.

We thank Hubert Höfer, State Museum of Natural History, Karlsruhe, for identification of the spider via photo and for advice on the manuscript; Volkswagen Stiftung for financial support; the Sarawak Forest Department for research permit (Number 38/2006, dated 3.8.2006.) and the staff of Gunung Mulu National Park, for support with logistics.

HYLA CHRYSOCELIS (Cope's Gray Treefrog). **OCULAR PATHOLOGY**. Ophthalmological disorders have been recorded in most vertebrates. Often, the animals in which these lesions have been described have been in captivity for varying lengths of time. However, it is unusual for such lesions to be discovered in wild populations. This disparity in discovery (not necessarily *incidence*) is probably because the condition may predispose the subject to predation or make it unable to compete successfully for resources. Captive animals are subject to observation and, thus, increased detection of ocular abnormalities. Intraocular inflammation, including panophthalmitis and uveitis have been reported in amphibians and reptiles (Zwart 1985. *In* R. Ippen et al. [eds.], Sinnesorgane: Erkrankungen der augen; Haut und anhangs-organe, pp. 250–269. Akadamie Verlag, Berlin (DDR); Millichamp and Jacobson 1986. *In* R. N. Kirk [ed.], Current Veterinary Therapy IX. Small Animal Practice, Ophthalmic Diseases of Reptiles, pp. 621–623, W. B. Saunders Company, Philadelphia, Pennsylvania; Frye 1991. *In* F. L. Frye [ed.], Husbandry, Medicine and Surgery in Captive Reptiles, Ophthalmic Conditions, 2nd Edition, Vol. 2, pp. 326–244. Krieger Publ. Co., Malabar, Florida; Lawton 1993. *In* S. M. Peterson-Jones and S. M. Crispin [eds.], Manual of Small Animal Ophthalmology, Ophthalmology of Exotic Species, British Small Animal Veterinary Association, Cheltenham, United Kingdom; Frye and Williams 1995. Self-Assessment Colour Review of Reptiles and Amphibians. Manson Publ., Ltd., London, United Kingdom, 192 pp.). The alteration of the crystalline lens, in the form of subcapsular lenticular disorganization, is well known in human ophthalmology (Hogan and Zimmerman 1962. Ophthalmic Pathology, 2nd Edition. W.B. Saunders Company, Philadelphia, Pennsylvania, pp. 344–468) but less often encountered (or recognized) in herpetological medicine.

An adult male *Hyla chrysoscelis* (50 mm SVL) was collected alive on 16 September 2000 by CTM in the South Texarkana/Liberty-Eylau area of Bowie County, Texas, USA (33.3716°N, 94.0733°W, elev. 92.1 m). The left eye was grossly enlarged and discolored. After obtaining essential measurements, the frog was photographed (Fig. 1), and euthanized by immersion in a satu-

FIG. 1. Pre-euthanasia photograph of *Hyla chrysoscelis* with panopthalmitis; note the massively swollen and enlarged left eye.

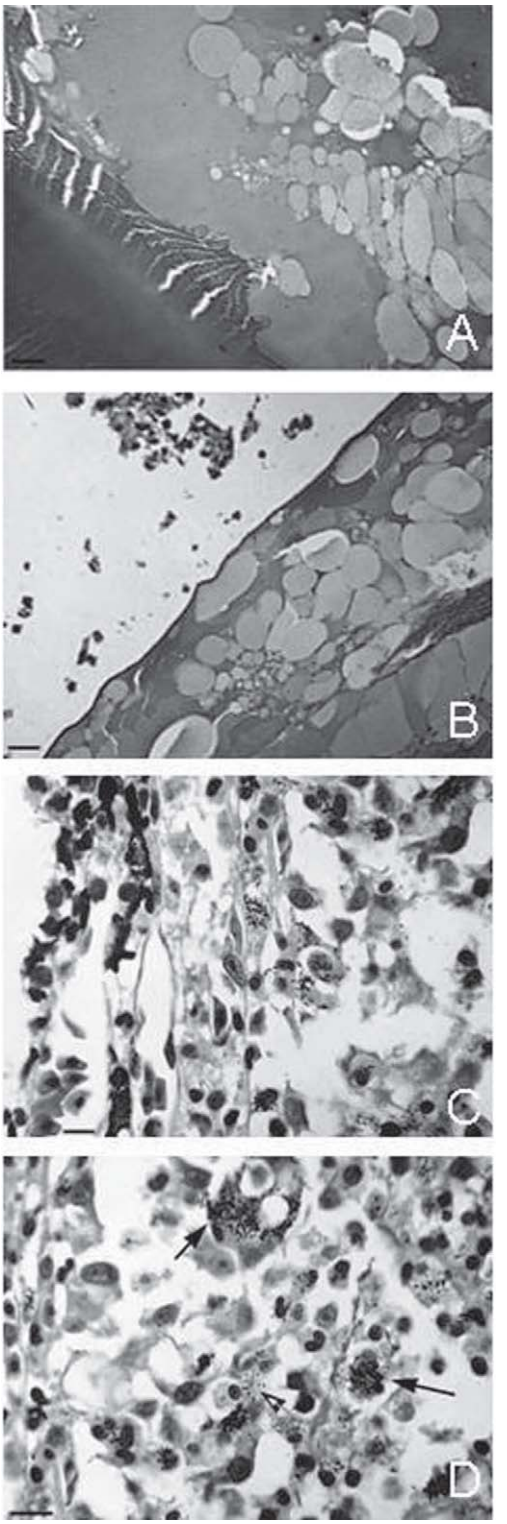

FIG. 2. A. Low power photomicrograph of the crystalline lens and intraocular fibrinous exudate adhering to a portion of the lens capsule. H & E. Bar = 20 µm. B. Photomicrograph of the affected lens. Note the degeneration and disruption of the normally lamellated concentric ring pattern and the pale-staining altered foamy areas. H & E. Bar = 20 µm. C. Photomicrograph of the intraocular exudate. Brown & Brenn. Bar = 30 µm. D. Another view of intraocular exudate; note large macrophages with engulfed bacteria and melanin pigment (solid black arrows) and individual bacteria (open black and white arrow). Brown & Brenn. Bar = 30 µm.

rated chlorobutanol (Chloretone®, Ward's Natural Science, Rochester, New York) solution (Etheridge 1958. Methods for Preserving Amphibians and Reptiles for Scientific Study. Mus. Zool., Univ. Michigan, Ann Arbor, Michigan, 18 pp.). The eye was enucleated, preserved in 10% neutral buffered formalin, and submitted for routine histopathological processing. A single hematoxylin and eosin stained section was examined by light microscopy and photographed by digital photomicroscopy. Supplemental sections were cut on a rotary microtome at 7 µm and stained with Brown and Brenn's modification of Gram's stain (Leaver et al. 1977. J. Clin. Pathol. 30:290–291). The frog voucher is deposited in the Arkansas State University, Herpetological Museum as ASUMZ 25326.

The anterior and posterior chambers of the eye were filled with a highly cellular exudate consisting of predominately mixed mononuclear inflammatory leukocytes comprised of lymphoplasmacytes, large histiocytic macrophages, a few heterophil granulocytes, and tenuous strands of fibrin that often adhered to the lens capsule (Figs. 2A–B). The crystalline lens had lost much of its normal concentric onion-like lammelated architectural pattern; the affected lens substance was lighter staining and possessed a patchy and foamy appearance (Figs. 2A–B). Small mononuclear cells were found adjacent to the lens capsule and numerous large macrophages with engulfed numerous Gram-negative and fewer numbers of Gram-positive bacteria were identified (Figs. 2C–D). In addition, engulfed melanin pigment granules were observed (Fig. 2D).

Ophthalmologic disorders have been recorded for many vertebrate species. Often, the animal involved is a captive and, thus, its ocular disease is more readily observed during daily animal care and maintenance. In this case, the affected frog was wild-caught, having already developed its severe ophthalmologic condition. In addition, 20 additional *H. chrysocelis* from the same site were not found to have this condition or any other noticeable gross pathology. Except for the finding of intra- and extracellular coccobacillary bacteria within the uvietic exudate, the etiology of the severe inflammation and subsequent lens disruption is unknown but, it is noteworthy because of its severity. Certainly, trauma associated with the introduction of pathogenic bacteria is a strong possibility. Had the frog escaped septicemic dissemination of the infection, it is conjectural as to whether the frog could have survived after having lost vision in one eye; however, there have been recorded instances of other wild-caught frogs after having lost the sight of an eye due to trauma, corneal, and lenticular opacities (Frye and Williams, *op. cit*.) Therefore, it can be surmised that in these cases binocular vision was not essential for prey capture and survival under wild conditions.

CTM thanks the Texas Parks and Wildlife Department for Scientific Collecting Permit No. 42-02 and S. E. Trauth (ASUMZ) for curatorial assistance.

LEPTODACTYLUS MELANONOTUS (Sabinal Frog). **DIET**. Some species of the Leptodactylidae are known for diverse diets (Savage 2002. Amphibians and Reptiles of Costa Rica. Univ. Chicago Press, Chicago, Illinois) and have tadpoles known for their intraspecific cannibalism (Silval et al. 2005. J. Nat. Hist. 39[7]:555–566). Herein we document a previously unknown scavenging habit of *Leptodactylus melanonotus*. In November 2005 in a Lowland Tropical Wet Forest in the northeastern coast of Costa Rica near Barra del Colorado, an adult male *L. melanonotus* was found advertising on the periphery of a desiccated ephemeral pool. The pool contained 48 dead, newly hatched *Rana vaillanti* tadpoles. Upon capture the *L. melanonotus* exhibited signs of a recent meal, and while being measured regurgitated 17 newly hatched *R. vaillanti* tadpoles. Among the stomach contents was an assortment of small springtail (Collembola) body parts and an intact aquatic Belostomatidae (Hemiptera). The adult frog weighed 3.5 g after regurgitating the tadpoles, and the regurgitated tadpoles totaled 2.3 g wet weight (the frog consumed 65% of its own body weight in tadpoles). The specimen and its stomach contents were deposited in the University of Costa Rica (UCR) collections within the Cãno Palma Biological Station specimens. To our knowledge this is the first record of consumption of tadpoles of another anuran species by adult *L. melanonotus*.

We thank M. Springer (University of Costa Rica) and F. St. Ours (University of Massachusetts, Boston) for help in invertebrate identification, Xavier Guevara of the Ministerio de Recursos Naturales Energia y Minas for permits, and the Canadian Organization for Tropical Education and Rainforest Conservation for permission to study at Caño Palma Biological Station.

RANA CASCADAE (Cascades Frog). **ALBINISM.** On 5 Aug 2002, we observed eight albino *Rana cascadae* larvae at a pond (65 m × 100 m; < 1 m deep) located 1.2 km NNW of Three Creek Lake, Deschutes County, Oregon, USA (44.1119444°N, 121.6313889°W; elev. 1960 m). Five albino larvae were captured and SVL measured (average SVL 25.4 mm, range 24–27 mm) and developmental stage estimated (stage 28–39; Gosner 1960. Herpetologica 16:183–190). During the survey, we observed 10 *R. cascadae* larvae with normal pigmentation that were of similar size and stage as the albino larvae. Albino larvae had a slight orangish hue in their eyes and throughout the body, typical of albinos of other species (Dyrkacz 1981. SSAR Herpetol. Circ. No. 11, 31 pp.). The brain, spinal column, internal organs, and almost completely developed forelegs were clearly visible through nearly transparent skin. We collected one albino larva (JC Braly Vertebrate Collection, Oregon State University 01550). We returned to the site on 16 Aug 2002 and collected a second albino larva and one non-albino larva. These two larvae transformed in the lab and died after 13 months.

In the only record of albinism in *R. cascadae* we were able to find, Altig and Brodie (1968. Wasmann J. Biol. 26:241–242) reported 13 albino larvae from 1965 and five from 1966 at a small pond "near Three Creek Lake, Deschutes County, Oregon." We were unable to confirm the exact pond through review of the museum records or communication with the authors. *Rana cascadae* breed in at least three lentic sites within 1.5 km of our site (C. Brown, unpubl. data: BM, pers. obs.). Nonetheless, our observations suggest the presence of albinos within a frog population > 35 years after original description. Our literature survey revealed only one report of albinism in the same anuran population in > 1 year (*Pseudacris triseriata* in two consecutive years; Corn 1986. J. Hered. 77:164–168).

This work was supported by the USGS State Partnership Program and the Amphibian Research and Monitoring Initiative (ARMI). We thank S. Borrego for field assistance, and two anonymous reviewers for their comments. All animals were handled under an Oregon Dept. of Fish and Wildlife scientific collecting permit.

RANA CATESBEIANA (American Bullfrog). **LITHOPHAGY**. Gravel, sand, and plant matter have been documented in *R. catesbeiana* stomachs during numerous diet studies. Korschgen and Moyle (1955. Amer. Midl. Nat. 54[2]:332–341) documented a variety of plant material and a small amount of gravel in *R. catesbeiana*. In Arkansas, McKamie and Heidt (1974. Southwest. Nat. 19:107–111) found a 15.9 g rock and plant matter in 28% of the stomachs examined. Plant material, rocks, and gravel are likely ingested accidentally.

On 8 June 2006, an adult *R. catesbeiana* was collected ca. 15 mi. SE of Mena, Arkansas, USA in a mineshaft ca. 18 m from the entrance. Upon collection it was apparent that it had a full stomach. Dissection revealed a single salamander skeleton (presumably *Plethodon caddoensis*), a small piece of wood, and inorganic matter including rocks and grit. The wood's mass was 0.07 g. The inorganic material ranged from tiny grains to large pebbles. There were 34 rocks totaling 12.27 g. Average mass was 0.36 g/rock (range 0.05–1.63 g) not including the fine grit.

This frog likely ingested the gravel while attempting to feed on salamanders that frequent the mineshaft. The specimen is deposited in the herpetology collection at the Arkansas State University Museum of Zoology (ASUMZ 30143).

RANA CLAMITANS (Bronze Frog). **RANID AGGRESSION AND INTERSPECIES AMPLEXUS**. On 3 July 2007, we observed and video-recorded inter- and intra-specific aggressive behavior of two male Bronze Frogs (*Rana clamitans clamitans*) and a male-female pair of Southern Leopard Frogs (*R. sphenocephalus*) in amplexus. The interactions occurred in the shallows of a slow moving creek in Santa Rosa County, Florida, USA, at ca. 1300 h and lasted for > 45 min. We first observed the behavior when the two Bronze Frogs began calling with increased frequency and then noticed one Bronze Frog aggressively moving (i.e., chasing) towards the pair of leopard frogs. The pair of leopard frogs submerged and crawled along the bottom of the creek, apparently to avoid the male Bronze Frog. However, each time they emerged, the Bronze Frog would reinitiate aggressive chasing and calling. After 12 min, the second male Bronze Frog moved toward the attacker and both frogs began grappling and ramming their heads together. Every 1–10 sec they would vocalize and jump between aggressive behaviors. After ca. 46 sec, the first Bronze Frog (and the larger of the two) retreated. The second, smaller Bronze Frog then chased the leopard frogs, which continued submerging and emerging to evade the aggressor. After another 50 sec of chase, the Bronze Frog amplexed the pair of leopard frogs (i.e., the male) using axillary amplexus. Next, the male leopard frog emitted a release call while the female leopard frog crawled along the bottom of the creek, carrying both males. The Bronze Frog remained amplexed for 96 sec before the first Bronze Frog returned and physically removed the amplexed Bronze Frog from the leopard frogs. Finally, the leopard frogs traveled a few more feet and the female slowly began depositing her eggs while the Bronze Frogs resumed their intra-specific aggression. After another 120 sec, the egg deposition ceased, and the larger Bronze Frog again chased the pair of leopard frogs. The leopard frogs quickly separated and retreated in different directions and the Bronze Frog eventually abandoned his pursuit and left the area.

SPEA HAMMONDII (Western Spadefoot). **PREDATION AND USE AS BURROW DECORATIONS**. During 19–22 April 2004, I observed two breeding pairs of Western Burrowing Owls (*Athene cunicularia hypugaea*) located 20 m apart within a vernal pool system near Goshen, Tulare Co., California, USA (36.3451°N, 119.3991°W, NAD83/WGS84, 88 m elev.). Each pair used a network of burrows clustered 1–3 m apart. The primary burrow used by the pair at each cluster was decorated with domestic sheep dung, skunk (*Mephitis mephitis*) fur, and desiccated remains of *Spea hammondii*. The entrances of the burrows in each cluster exhibited 3–5 toads in various states of disarray. Hindquarters were present without the head or thoracic cavity, and nearby were the heads and upper bodies either still attached or in separate pieces. The soft organs of the thoracic cavity were missing. Both the Western Spadefoot and Western Burrowing Owl are species of special concern in California.

Burrowing Owls commonly decorate their burrows with a variety of items, such as dung, grass, paper, cotton, and dried moss (Levey et al. 2004. Nature 431:39; Smith and Conway 2007. Anim. Behav. 73:65–73). Flattened mummified remains of the Southern

Toad (*Bufo terrestris*), assumed to be roadkills, have been found at Burrowing Owl burrows as well (D. Levey, pers. comm.). The *S. hammondii* were readily available to the Burrowing Owls because their burrows were within a vernal pool system, a habitat where spadefoots commonly occur.

The Burrowing Owl has been infrequently reported to prey on toad species (Haug et al. 1993. Burrowing Owl. *Athene cunicularia*. *In* A. Poole and F. Gill [eds.], The Birds of North America, No. 61. Academy of Natural Sciences, Philadelphia, and American Ornithologists' Union, Washington, D.C.). Although toads commonly have toxins in their dorsal surfaces, owls and other predatory birds are able to avoid these toxins by consuming the vulnerable ventral portions (Olson 1989. Copeia 1989:391–397). Ervin et al. (2007. Herpetol. Rev. 38:197–198) were the first to report Burrowing Owl predation on Western Spadefoot adults, however, only the tongues were consumed in those cases. In this instance, the Burrowing Owl may have captured and consumed portions of *S. hammondii* and then used their remains as burrow decorations.

TESTUDINES – TURTLES

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **NESTING**. *Dermochelys coriacea* is currently classified by the Brazilian Ministry of the Environment and the IUCN (World Conservation Union) as critically endangered. Although occasional nesting has been observed on the Brazilian coast (see Barata and Fabiano 2002. Marine Turtle News. 96:13–16), the only site reporting regular Leatherback nesting is located in a restricted area on the northern coast of the state of Espírito Santo, with an extent of ca. 200 km (18.35°S, 39.67°W and 20.07°S, 40.17°W) (Marcovaldi and Marcovaldi 1999. Biol. Conserv. 91:35–41). Here, we present the first record of *D. coriacea* nesting on the Brazilian northern coast. On 17 July 2004 at about 1800 h, within the limits of the Environmental Protection Area of the Delta do Parnaíba, Arrombado beach, Luís Correia city, state of Piauí (02.9097°S, 41.5325°W; 3 m elev.; Datum SAD69 IBGE/BR), we observed one *D. coriacea* deposit a clutch of 108 eggs. The nest was monitored after oviposition; 96 hatchlings emerged after an incubation period of 58 days (Fig. 1). Local fishermen also have reported the sporadic presence of *D. coriacea* nesting along Piaui's beaches. Although this species may be expected in Piauí state, considering its distribution in the neighboring states of Ceará and Maranhão (Barata et al. 2004. J. Mar. Biol. Assoc. U.K. 84:1233–1240), this is the first documented record of this species nesting in Piauí state.

GLYPTEMYS INSCULPTA (Wood Turtle). **HATCHLING BEHAVIOR**. Hatchlings of *Glyptemys insculpta* typically emerge from the nest in late summer and early fall (Buech et al. 2004. Herpetol. Rev. 35:54; Harding and Bloomer 1979. Bull. New York Herpetol. Soc. 15:9–26; Tuttle and Carroll 2005. Northeast. Nat. 12:331–348), even at the northern limits of their range (Brooks et al. 1992. Can. J. Zool. 70:462–469; Walde et al. 2007. Herpetol. Conserv. Biol. 2:49–60). In New Hampshire, newly-emerged hatchling *G. insculpta* were observed to migrate long distances (up to 445 m), spending several days and nights on land before reaching aquatic habitats where they are presumed to hibernate (Tuttle and Carroll, *op. cit.*). Parren and Rice (2004. Northeast. Nat. 11:229–233) reported a suspected terrestrial overwintering by a neonatal *G. insculpta* in Vermont.

As a follow up to a study of the nesting ecology of *G. insculpta* (Walde et al. 2007, *op. cit.*), hatchlings were tracked using fluorescent pigments (Butler and Graham 1993. Herpetol. Rev. 24:21–22) as they dispersed from nests in August through October 1997.

Hatchlings often used forms as resting places during periods of inactivity. Typically, forms consisted of a small excavation into which the turtle could fit; often under vegetation, rocks, or other objects. When in a form, hatchlings were observed to withdraw their head and limbs into their shells. Seven hatchlings emerged from one nest on 23 September 1997 and all hatchlings were treated with fluorescent pigments and subsequently released. Nocturnal tracking revealed five of the seven hatchlings were still on land, but not in forms or under any insulative material. At 0730 h on 24 September 1997, there was frost on the ground, ice on puddles, and the air temperature, measured with a handheld thermometer at the nesting site was -3°C. The five turtles were in the same position as the previous night, and all of them had their limbs and necks extended and were covered in ice crystals. Upon handling, two individuals were rigid, as if they were frozen solid, with their limbs rigid and extended. Both turtles were placed back where they were found. By 1100 h the temperature was well above freezing and four of the five hatchlings had moved; whereas, the fifth hatchling was alive but had not moved. Air temperature remained above 0°C the following two nights, when four of the five hatchlings were still on land and dug into forms; a fifth hatchling was not re-located.

Natural freeze tolerance, defined as the ability to survive freezing of body tissues under ecologically-relevant conditions, has been reported for several species of frogs, lizards, snakes, and turtles (Storey and Storey 1996. Ann. Rev. Ecol. Syst. 27:365–386). Hatchling turtles of several emydid species survive freezing to temperatures -3°C for at least 72 h (Costanzo et al. 2006. J. Comp. Physiol. B 176:697–707). Our observations suggest that hatchling *G. insculpta* can endure freezing at similar subzero temperatures, although we were not able to record actual body temperatures. In regions where overnight frosts occur during the fall emergence period, a tolerance for freezing of body tissues may increase survival of terrestrially migrating hatchling turtles.

Funding, equipment, and personnel for this research were generously provided to the St. Lawrence Valley Natural History Society by Parks Canada, Fondation de la Faune du Québec, and Société de la faune et des parcs du Québec.

GLYPTEMYS INSCULPTA (Wood Turtle). **MAXIMUM CLUTCH SIZE.** Gammons (1871. Amer. Nat. 4:53) reported a clutch size of 18 eggs for *Glyptemys insculpta*. Carr (1952. Handbook of Turtles: The Turtles of the United States, Canada, and Baja California. Cornell Univ. Press. Ithaca, New York) rejected the account however, assuming it to be some sort of "hallucination" because of the odd nesting behaviors described by Gammons. Nevertheless, Harding (1977. Herpetol. Rev. 8:34) subsequently reported a clutch size of 18 eggs for *G. insculpta* in Michigan.

During studies of the nesting ecology of *G. insculpta* in Québec, Canada (Walde et al. 2007. Herpetol. Conserv. Biol. 2:49–60), we observed a record clutch for this species. On 17 June 1997 at 0930 h, a *G. insculpta* was observed constructing a nest. It was not possible to count the number of eggs, as approaching would have disturbed the other Wood Turtles present in the nesting area (Walde et al. 2007, *op. cit.*). Seventeen hatchlings emerged from this nest cavity; 16 on 27 August 1997, and an additional one on 30 August 1997. When the nest was excavated on 9 September 1997, there were 17 egg shells and an additional three eggs with dead embryos that were putrid and covered in fly larvae. Thus, the total clutch size was 20 eggs. The female that laid this clutch had a carapace length (CL) of 224 mm, plastron length (PL) of 214 mm, and mass of 1475 g. She was the largest of 39 females observed to nest during the two-year study, and was the second largest observed in the population of 83 females (Walde et al. 2003. Can Field-Nat. 117:377–388). Walde et al. (2007, *op. cit.*) reported that clutch size within this population was significantly positively correlated with CL, PL, and mass. There appears to be some level of geographic variation present, as maximal clutch sizes from northern populations tend to be larger than those from southern ones (Walde et al. 2007, *op. cit.*).

We acknowledge Parks Canada, Fondation de la Faune du Québec, and Société de la faune et des parcs du Québec for provided funding, equipment and personnel to the St. Lawrence Valley Natural History Society for this study. Many individuals assisted with this project, to them we are grateful. We specifically acknowledge Denis Masse of Parks Canada for logistical support while in the field.

GRAPTEMYS GEOGRAPHICA (Northern Map Turtle). **HABITAT.** *Graptemys geographica* is typically described as inhabiting larger, slow-moving rivers, and lakes with mud bottoms rather than small creeks and ponds (Conant and Collins 1998. A Field Guide to Amphibians and Reptiles of Eastern and Central North America. 3rd Edition. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.; Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington D.C. 578 pp.) Here I report two encounters of *G. geographica* in Marshall Co., Tennessee, in 2006 and 2007, in or near Bear Creek. These encounters happened at least 20 miles from the nearest large river (Duck River) and both encounters were with large females.

A mature female *G. geographica* was found during the morning of 23 April 2005 crossing Mooresville Highway (Highway 373) at a bridge (35.4545°N, 86.9304°W). This occurrence was after a heavy rain and water levels in Bear Creek were elevated. The reason for the turtle crossing the bridge was unclear; other than the creek, there are no other water sources in the direction from which she had presumably traveled, or in the direction she was moving. This large (though unmeasured) female was retrieved from the bridge, photographed, and released back into Bear Creek in the location that she was apparently headed.

The second *G. geographica* female was encountered in the afternoon of 1 June 2006 in the same general area, but was further away from the road and was further upstream (35.45005°N, 86.93107°W). This female, encountered while constructing a nest, was photographed but not otherwise disturbed. The water level in Bear Creek at the time was not abnormally elevated. The width of the creek nearest to where this female was found does not exceed 1.8 m and the depth does not exceed 0.3 m. The success of the nest was not determined because of time constraints.

Photo vouchers are deposited at Austin Peay State University Museum of Zoology: APSU 18305 (23 April 2005 record), APSU 18306 (1 June 2006 record).

MANOURIA IMPRESSA (Impressed Tortoise). **ENDOPARASITES.** *Manouria impressa*, a medium-sized, forest dwelling tortoise, ranges from Myanmar and Malaysia to Vietnam and China (Iverson 1992. A Revised Checklist with Distribution Maps of the Turtles of the World. Privately printed, Richmond, Indiana. 278 pp). To our knowledge, no endoparasites have been reported from *M. impressa*. The purpose of this note is to report an occurrence of the nematode *Cissophyllus roseus* in *M. impressa*.

Wild-caught *Manouria impressa* confiscated by the US Fish and Wildlife Service were sent to Zoo Atlanta for triage and veterinary care. *Manouria impressa* is a particularly difficult species to keep in captivity. Wild-caught tortoises often succumb to a myriad of illnesses (Innis C et al. 2006. J. Herpetol. Med. Surg. 16:49–52). The confiscated tortoises appeared in good health and had adequate body weight. They were kept in quarantine for 45 days. On a routine fecal examination, during the first week in quarantine, we found two male and four gravid female nematodes. The nematodes were fixed in alcohol and later cleared in lactophenol for microscopic examination during which they were identified as *Cissophyllus roseus*.

Railliet and Henry (1912. Bull. Soc. Path. exot., Paris. 5:251–259) described the nematode *Cissophyllus laverani* from an Indomalaysian tortoise, *Testudo emys* (currently *Manouria emys*) and in a second paper (Railliet and Henry 1915. Bull. Soc. Path. exot., Paris. 8:446–452) mentioned that the nematode *Cucullanus roseus* described by Leidy (1851. Proc. Acad. Nat. Sci., Philadelphia 5:205–210) from the tortoise *Manouria fusca* (currently *Manouria emys*) had greater affinity for the genus *Cissophyllus* than for the genus *Cucullanus*; however, synonymy was not established. Walton (1927. Proc. Acad. Nat. Sci., Philadelphia 79:49–163) revised the Leidy collection and did synonymize *Cucullanus roseus* with *Cissophyllus laverani*, the name becoming *Cissophyllus roseus*.

Prior to our observation, *Manouria emys* was the only known host for *C. roseus*. *Manouria impressa* represents a new host record and only the second host known for *C. roseus*. To our knowledge there are no life history studies for this nematode, but zoological institutions and those in the private sector should be aware of the possibility of infection when introducing wild-caught specimens into established collections.

STERNOTHERUS ODORATUS (Stinkpot) **MINIMUM SIZE / GROWTH**. On 26 April 2007 one of us (JKT) collected a juvenile *Sternotherus odoratus* using a dip net at Stump Lake, Jersey County, Illinois, USA (38.9912°N, 90.5554°W; NAD27 datum). This turtle had presumably hatched in 2006, and likely emerged from the nest in the fall of 2006, as this species typically does not overwinter in the nest (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 578 pp.). Most reports on turtle size present record maximum lengths (e.g., Blasus et al. 2004. Herpetol. Rev. 34:54; Lubcke and Wilson 2006. Herpetol. Rev. 37:339; Tucker et al. 2006. Herpetol. Rev. 36:453–455). Here we report on the smallest non-hatchling turtle. Despite the possibility that the turtle was active for some weeks or months, it was remarkably tiny (Fig. 1). It weighed 1.54 g and had a carapace length of 18.8 mm, a carapace width of 17.7 mm, a carapace height of 11.5 mm, and a plastron length of 13.8 mm (all measurements made using methods of Tucker et al. 2006, *ibid*.). This individual was much smaller than eight recently emerged hatchlings (= those with no scute annuli on the carapace scutes) caught in Stump Lake during fall of 2005 (29 September and 5 October) using minnow traps. These eight averaged 4.58 g in wet mass (SD = 0.74 g, range = 3.70–5.90g), 27.4 mm carapace length (SD = 1.92 mm, range = 25–30 mm), 24.0 mm in carapace width (SD = 2.14 mm, range = 21–27 mm), 14.5 mm in carapace height (SD = 1.31 mm, range = 12–16 mm), and 19.4 mm in plastron length (SD = 1.51 mm, range = 17–22 mm). This species grows rapidly after hatching. For instance, nine individuals in their first full season of growth (= those with one

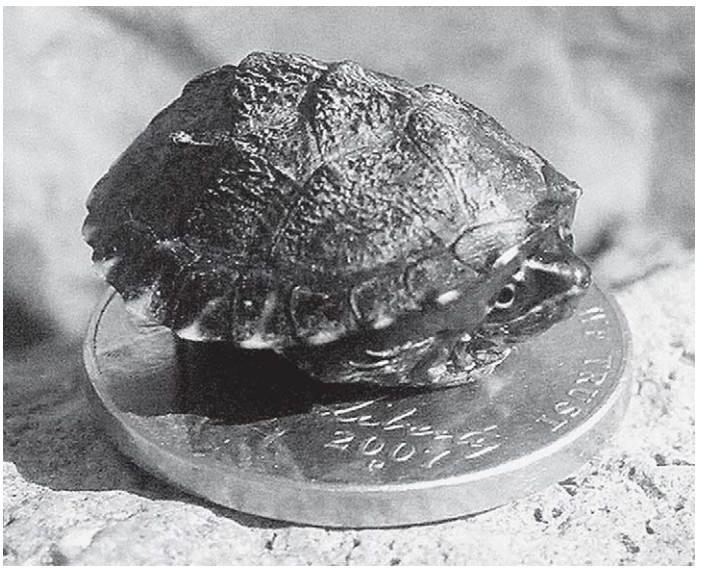

FIG. 1. Juvenile *Sternotherus odoratus* from Stump Lake, Jersey County, Illinois, placed on a U.S. nickel (21.15 mm in diameter) for scale.

scute annulus on the carapace scutes) from Stump Lake were caught between 30 June and 29 July 2005 with minnow traps. These juveniles had emerged from eggs laid in 2004. They averaged 10 g (SD = 0.80 g, range = 8.9–11.1 g) in wet mass, 34.3 mm in carapace length (SD = 1.22 mm, range = 32–36 mm), 30.2 mm in carapace width (SD = 1.20 mm, range = 29–32 mm), 19.2 mm in carapace height (SD = 0.67 mm, range = 18–20 m), and 24.8 mm in plastron length (SD = 1.09 mm, range = 24–27 mm). Thus juveniles from Illinois nearly double their size in the first full year after hatching. Reports on first year growth are few for this species (see Ernst et al. 1994, *op. cit.*, for a review). Nonetheless, Risley (1933. Pap. Michigan Acad. Sci. Arts Lett. 17:685–711) found that yearling Stinkpots averaged 32.5 mm in carapace length, similar to the 34.3 mm size we found.

The Stump Lake juvenile was smaller than 95 hatchlings from eggs induced from Jersey and Calhoun county females. These 95 eggs averaged 3.94 g in wet mass (SD = 0.47 g, range = 2.85–5.67 g) (see Tucker 1999. Bull. Maryland Herpetol. Soc. 35:61–75 for details on egg collection). The 95 hatchlings averaged 2.74 g in weight (SD = 0.32 g, range = 1.94–3.56 g), 22.8 mm in carapace length (SD = 1.15 mm, range = 19.6–25.2 mm), 16.7 mm in carapace width (SD = 1.44 mm, range = 12.8–20 mm), and 17.5 mm in plastron length (SD = 0.96 mm, range = 15.2–19.8 mm). These hatchlings were weighed and measured the day they left the egg (methods of Tucker et al. 2006, *op. cit.*). Carapace height was not measured for these hatchlings to avoid interference with residual yolk retraction.

Nonetheless, hatchlings of several species of Kinosternidae may leave the egg even smaller than the juvenile that we caught. Few published records of kinosternid hatchlings report mass, and the next smallest individual by weight was a hatchling Stinkpot that weighed 1.6 g (Mitchell 1994. The Reptiles of Virginia. Smithsonian Institution Press, Washington, D.C. 352 pp.). Many authorities report linear shell dimensions and several have reported hatchlings with carapace lengths smaller than 18.8 mm. These include *Sternotherus odoratus* with carapace length of 18.5 mm (Ernst et al. 1994, *op. cit.*; Mitchell 1985. Copeia 1985:941–949), *Kinosternon subrubrum* with carapace length of 16.7 mm, *K. baurii* with carapace length of 16.5 mm, and *K. flavescens* with carapace length of 17.7 mm (all from Ernst et al. 1994, *op. cit.*). These are, however, measurements of hatchlings fresh from the eggs and not of free ranging turtles such as the one we report. It is interesting that such genuinely minute juveniles only occur in North American Kinosternidae and apparently not in any non-North American turtles (see reviews by Pritchard 1979. Encyclopedia of Turtles. T.F.H. Publications, Inc. Ltd., Neptune, New Jersey, 895 pp.; Ernst and Barbour 1989. Turtles of the World. Smithsonian Institution Press, Washington, D.C., 313 pp.). Hatchlings tend to be much larger (25 mm + carapace length) in other turtle species (for a review of many worldwide species see Table 2 in Ewert 1979 (*In* Harless and Morlock [eds.], Turtles: Perspectives and Research. The embryo and its egg: development and natural history, pp. 333–413, John Wiley and Sons, New York). The adaptive significance for such small hatchlings has never been investigated and it may be simply a reflection of the small adult sizes of many kinosternids. Egg size can be strongly constrained in such small turtles (e.g. Tucker et al. 1978. Bull. Maryland Herpetol. Soc. 14:10–22; Congdon and Gibbons 1987. Proc. Natl. Acad. Sci. 84:4145–4147).

All hatchlings and juveniles that we examined were or will be released at the original collecting sites or at the collecting sites of the female parent. We thank Emily Dustman, Michael Avara, and Megan Dooling for help in collecting turtles. This research was partially funded by a grant to JKT from the National Great Rivers Research and Education Center, Richard E. Sparks, director of research and by support from the Illinois Natural History Survey, Great Rivers Field Station, John H. Chick, Director.

SQUAMATA – LIZARDS

ANOLIS AENEUS (Grenadian Bush Anole), ***ANOLIS RICHARDII*** (Grenadian Tree Anole). **NECTARIVORY / POLLINATION**. Recent observations (e.g., Perry and Lazell 1997. Herpetol. Rev. 28:150–151) have contributed to the general notion that island-dwelling lizards may both feed on nectar and act as pollinators (Olesen and Valido 2003. Trends Ecol. Evol. 18:177–181). Here, we report accounts of nectarivory and presumptive pollinating behavior on two native plant species, *Charianthus grenadensis* and *Marcgravia umbellata*, by *Anolis aeneus* and *Anolis richardii*, in Grenada, Lesser Antilles. Our observations were made in the elfin forest along the Mt. Qua Qua trail within Grand Etang National Park in the montane interior (elev. 690–710 m) of Grenada.

Between 0828 and 0830 h on 22 June 2006, we observed *A. aeneus* visiting two flowers of *C. grenadensis*. This generalized anole (Germano et al. 2003. Caribb. J. Sci. 39:68–76) was slowly sliding its head into the broad opening of the flowers and licking nectar from the bottom of these. In the process, the anole touched both anthers and stigma with its head. *Charianthus grenadensis*, endemic to montane Grenada, is believed to be adapted for hummingbird pollination (Penneys and Judd 2005. Syst. Bot. 30:559–584) as it displays several classic ornithophilous features, e.g., bright red corolla, no obvious scent, and a large amount of diluted nectar (24-h sample of bagged flowers; volume: = 53.0 ± 24.8 µl; concentration: = 11.6 ± 0.9% weight/weight sucrose equivalents, N = 13; AT and LHA, unpubl. data).

On 22 June 2006, we observed two *A. richardii* visiting a single inflorescence of *M. umbellata*. The length of the visits was 15 and 6 min (1135–1150 and 1242–1248 h). Both anoles exhibited pollinating behavior, i.e., the head and dorsal part of the body brushed against the anthers and stigma of the flowers as they licked nectar from several of the pendulous tubular nectaries of the inflorescence (Fig. 1). *Marcgravia umbellata*, restricted to the Lesser Antilles, is adapted for bird and/or bat pollination (Dressler 1997. Curtis's Bot. Mag. 14:130–136; Zusi and Hamas 2001. Caribb. J. Sci 37:274–278). Its flowers have no scent, a large amount of dilute nectar (24-h sample of bagged flower; volume = 119.5 µl; concentration = 9% weight/weight sucrose equivalents; N = 1; AT and LHA, unpubl. data) and dull brown-green colors.

Our observations reveal that *Anolis* lizards have the potential to pollinate both *C. grenadensis* and *M. umbellata*. Nectar-feeding

FIG. 1. *Anolis richardii* visiting *Marcgravia umbellata*. The lizard was feeding on nectar and touching both anthers and stigma. Photo by Allan Timmermann.

lizards acting as pollinators on islands may result from reduced insect abundance, fewer predators and less interspecific competition than on comparable mainland environments, allowing density compensation and niche broadening by island lizards (Olesen and Valido 2003. Trends Ecol. Evol. 18:177–181). In the Caribbean, hurricanes may be an additional factor offering lizards the opportunity to expand their diet to include energy-rich nectar from typically bird-pollinated flowers. Hurricanes can cause nectarivorous bird populations to crash, subsequently limiting pollination and resulting in surplus nectar in bird-pollinated flowers (Rathcke 2000. Ecology 81:1951–1958). Whether lizards are important backup pollinators of otherwise bird-pollinated plants in the aftermath of hurricanes needs investigation.

We are grateful to the Department of Forestry and National Parks, Ministry of Agriculture, Grenada for help throughout our fieldwork in Grenada. We thank A. Valido for comments and R. Powell for kindly identifying the *Anolis* lizards. Funding was provided by Aarhus University Faculty of Natural Science, Knud Højgaard, Augustinus and Carlsberg Foundations, the Danish National Science Research Council and WWF-Denmark/Novozymes.

ASPIDOSCELIS COSTATA HUICO (Blue-chested Whiptail). **REPRODUCTION**. *Aspidoscelis costata huico* (*sensu* Reeder et al. 2002. Am. Mus. Novit. 3365:1–61) is among many named, but biologically poorly known reptiles from remote areas of México. Zweifel (1959. Bull. Am. Mus. Nat. Hist. 117:57–116) described the subspecies based on 193 specimens from the type locality (Peñitas, 19.2 km SE of Rosamorada, Nayarit) and other mainland sites in the states of Sinaloa, Nayarit, Jalisco, and Zacatecas; and Isla Isabel, Nayarit. Here, I provide reproductive data (clutch ranges and mean ± SE, SVL ranges and mean ± SE) for a subspecies which Zweifel (*op. cit.*) noted only maximum sizes of males and females (both 106 mm SVL) and described a mating incident observed at La Vuelta, Nayarit, on 25 August 1957 by T. H. Lewis.

I examined 255 *A. c. huico* from the California Academy of Sciences (CAS) collection obtained by A. E. Greer and F. W. Burley in two Mexican states: Sinaloa, 45.4 km E of jct Hwy 40 (Durango Road) and Hwy 15 on Hwy 40 [10 June 1963 (CAS 114865–114876, N = 12); Hwy 40, 17.0 km E of jct Hwy 15 [30 June 1963 (CAS 115230–115256, N = 27)]; 9.9 km E of jct Hwys 15 and 40 on Hwy 40 [30 June 1963 (CAS 115210–115221, N = 12)]; Hwy 40 at 39.7 km E of jct Hwy 15 [10 June 1963 (CAS 114877–114833, N = 7)]; 5.3 km W of Hwy 15 on dirt road 13.3 km N of Escuinapa [3 July 1963 (CAS 115295–115301, N = 7)]; 11.1 km E of jct 15 and Hwy 40 on Hwy 40 [14 June 1963 (CAS 114961–114991, N = 31)]; 25.9 km S of Escuinapa on Hwy 15 [2 July 1963 (CAS 115269–115287, N = 19)]; Nayarit, Arroyo de Rifilion, 9.0 km N of Compostela [13 May 1963 (CAS 114391–114416, N = 26)]; Laguna Santa Maria Road, 6.6 km NE of jct Hwy 15 and Laguna Santa Maria Road [28 May 1963 (CAS 114664–14669, N = 6)]; 1.3 km N of Navarette on Sauta Road [27 June 1963 (CAS 115154–115174, N = 21)]; 32.3 km S of Río Acoponeta on Hwy 15 [23 June 1963 (CAS 115036–115071, N = 36)]; 1.8 km S of Río Canas on Hwy 15 [2 July 1963 (CAS 115262–115267, N = 6); 23.0 km W of jct Mexcaltitan and Hwy 15 on Mexcaltitan Road [28 June 1963 (CAS 115194–115199, N = 6)]; end of Santiago Ixcuintla Road, 45.6 km W of jct of Santiago Road and Hwy 15 [7 July 1964 (CAS 95372–95389, N = 18)]; Laguna Santa Maria [26 June 1964 (CAS 95326–95346, N = 21). I obtained size (as SVL to the nearest 1 mm) for all except 41 males in the CAS sample. Females were dissected to identify the number and measure oviductals eggs and ovarian follicles.

The ca. 3:1 sex ratio (187 males:68 females) in *A. c. huico* was on the order of the ca. 2:1 (129 males:64 females) observed in *A. c. nigrigularis* (Walker 2008. Herpetol. Rev., *in press*). Only 10 (21.7%, 6 measurable clutches) of 46 gravid females contained oviductal eggs; all others had yolked ovarian follicles of 3.5–10.0 mm in diameter. Bias in the sex ratio of both subspecies may pertain to secretive female behavior during egg maturation and oviposition that make them less susceptible to collection than other adults. Alternatively, shorter life expectancy in females is a non-mutually exclusive explanation that may also contribute to the male-biased sex ratio. The latter may be reflected by the relative male-female numbers, respectively (in parens), by sizes (as 10-mm SVL increments where applicable) in the CAS sample: 50–59 mm (2:0); 60–69 mm (9:4); 70–79 mm (23:23); 80–89 mm (37:24); 90–99 mm (32:13); 100–109 mm (4:4); 110–118 mm (39:0). Assuming any secretive behavior by adult females is unrelated to their size, *A. c. huico* appears strongly sexually dimorphic in favor of males.

Females of *A. c. huico* appear to attain reproductive maturity at a small size (< 70 mm SVL) similar to *A. c. barrancarum* in south-

western Chihuahua (Walker et al. 2004. Herpetol. Rev. 34:366) and *A. c. nigrigularis* in Sinaloa (Walker 2008, Herpetol. Rev., *in press*). In *A. c. huico*, 2 females 67–69 mm SVL had clutches of 2–3 (mean = 2.5). Among females 70–79 mm SVL, 13 (56.5%) were gravid; clutch size was 2–5 (mean = 3.2, N = 13). Among females 80–89 mm SVL, 17 (70.8%) were gravid; clutch size was 2–6 (mean = 4.4, N = 17). Among females 90–99 mm SVL, 12 (92.3%) were gravid; clutch size was 3–8 (mean = 5.6, N = 12). Among females 100–105 mm SVL 2 (50%) were gravid; clutch size was 5–7 (mean = 6.0, N = 2). For the period 13 May–7 July 1964, 46 females with data had clutches (sample size in each category in parens) of 2 (4), 3 (11), 4 (13), 5 (6), 6 (7), 7 (4), and 8 (1) eggs; mean clutch size and SVL for these females were 4.4 ± 0.23 (2-8) eggs and 83.5 ± 1.27 (67–105) mm, respectively. A moderately strong relationship exists between clutch size and SVL (adjusted $r^2 = 0.50$). Data for the CAS sample established these additional reproductive characteristics for *A. c. huico*: SVL of all adult males, 92.7 ± 1.21 (67–118, N = 131) mm; SVL of all adult females, 83.6 ± 1.42 (62–105, N = 66); oviductal egg dimensions in 6 (60%) females with oviductal eggs, 8.2 ± 0.44 × 14.4 ± 0.45 (7.5–10.0 × 13–16) mm; reproductive season, minimally May–July (this study) into late August (Zweifel, *op. cit*.); and reproductive potential, multiple clutches based on maturation of both sexes at small body sizes within the long activity cycle near the northern fringe of the tropics in Sinaloa, Nayarit, and Jalisco. Collecting data for the CAS sample also revealed that *A. c. huico* achieves high population densities at numerous mainland sites and on Isla Isabel (based on CAS 59136–59295, N = 160) within an area occupied by a congener (*A. lineatissima duodecemlineata*; Zweifel, *op. cit*.) only at San Blas, Nayarit.

I thank Robert C. Drewes (CAS) for the opportunity to examine specimens in his care.

ASPIDOSCELIS COSTATA NIGRIGULARIS (Sinaloa Black-throated Whiptail Lizard). **REPRODUCTION**. *Aspidoscelis costata nigrigularis* (*sensu* Reeder et al. 2002. Am. Mus. Novit. 3365:1–61) is among many named, but biologically poorly known reptiles from remote areas of México. Zweifel (1959. Bull. Am. Mus. Nat. Hist. 117:57–116) described the subspecies based on 47 specimens from the type locality (16.8 km NW of Culiacán) and other sites in western Sinaloa. Here, I provide reproductive data (clutch ranges and ± SE; SVL ranges and ± SE) for a subspecies which Zweifel (1959, *op. cit.*) noted only minimum size at maturity for females (62 mm SVL), maximum sizes for females (84 mm SVL) and males (114 mm SVL), and reproductive season between 18 July and August 20 (based on 3 gravid females).

I examined 196 *A. c. nigrigularis* from the California Academy of Sciences (CAS) collection obtained by A. E. Greer and F. W. Burley at 12 sites in Sinaloa over 13 days in 1963: 1.9 km E of La Cruz [6 July (CAS 115304–115313, N = 10)]; 8.5 km E of La Cruz [6 July (CAS 115314–115327, N = 14)]; 21.4 km S of San Lorenzo, Hwy 15 [10 July (CAS 115365–115384, N = 20)]; 14.4 km N of San Lorenzo, Hwy 15 [11 July (CAS 115385–115410, N = 26)]; 12.5 km S of Río San Lorenzo, Hwy 15 [11 July (CAS 115417–115435, N = 19)]; 12.8 km S of Culiacán, Hwy 15 [12 July (CAS 115440–115456, N = 17)]; 1.9 km N of El Dorado on El Dorado Road [13 July (CAS 115460–115482, N = 23)]; 3.5 km W of jct of road 4.5 km S of Navolato [14 July 1963 (CAS 115509–115523, N = 15)]; 22.9 km S of jct of El Dorado and Navolato Roads [14 July (CAS 115524, N = 1)]; 33.6 km N of Río Culiacán, Hwy 15 [17 July (CAS 115528–115546, N = 19)]; 11.4 km N of Río Evora Nocorito, Hwy 15 [18 July (CAS 115584–115596, N = 13)]; 85.8 km N of Río Culiacán, Hwy 15 [18 July (CAS 115611–115629, N = 19)]. I obtained size (as SVL to the nearest 1 mm) and gender on all except 3 animals. Females were dissected to identify the number and measure oviductal eggs and ovarian follicles; 5 females were too damaged internally to permit this assessment.

The ca. 2:1 sex ratio (129 males:64 females) in *A. c. nigrigularis* was on the order of the ca. 3:1 (187 males:68 females) observed in *A. c. huico* (Walker 2008. Herpetol. Rev., *in press*). Only 9 (20.5%) of 44 undamaged gravid females of *A. c. nigrigularis* contained oviductal eggs; all others had yolked ovarian follicles 3.5–9.5 mm in diameter. Bias in the sex ratio in both subspecies may pertain to secretive female behavior during egg maturation and oviposition that make them less susceptible to collection by humans than other adults in the population. Alternatively, shorter life expectancy in females is a non-mutually exclusive explanation that may also contribute to the male-biased sex ratio. The latter may be reflected by the relative male-female numbers, respectively (in parens), by sizes (as 10 mm SVL increments where applicable) in the CAS sample: 50–59 mm (3:2); 60–69 mm (15:12); 70–79 mm (25:13); 80–89 mm (18:20); 90–99 mm (20:14); 100–109 mm (26:3); 110–118 mm (22:0). Assuming any secretive behavior by adult females is unrelated to their size, *A. c. nigrigularis* appears strongly sexually dimorphic in favor of of males.

Females of *A. c. nigrigularis* appear to attain reproductive maturity at a small body size similar to *A. c. barrancarum* in southwestern Chihuahua (Walker et al. 2003. Herpetol. Rev. 34:366). In *A. c. nigrigularis*, 5 females 62–68 mm SVL had clutches of 1–2 (mean = 1.8) eggs. Among females 70–79 mm SVL, 11 (85%) were gravid; clutch size was 2–4 (mean = 2.9, N = 10). Among females of 80–89 mm SVL, 18 (95%) were gravid; clutch size was 3–7 (mean = 4.8, N = 14). Among females 90 mm SVL, all were gravid; clutch size of females 90–99 mm SVL was 4–7 (mean = 5.8, N = 12), but was 6–7 (mean = 6.7, N = 3) for females 100–105 mm SVL. For the period 6–18 July 1963, 44 females with data had clutches (sample size in each category in parens) of 1 (1), 2 (8), 3 (4), 4 (10), 5 (6), 6 (10), and 7 (5) eggs; mean clutch size and SVL for these females were 4.4 ± 0.26 (1–7) eggs and 83.6 ± 1.63 (62–105) mm, respectively. Clutch size was strongly correlated with SVL (adjusted $r^2 = 0.71$). Data for the CAS sample established these additional reproductive characteristics: SVL of all adult males, 90.8 ± 1.45 mm (range: 62–118, N = 123) mm; SVL of all adult females, 83.6 ± 1.42 mm (range: 62–105, N = 54) mm; oviductal egg dimensions in 9 females with oviductal eggs, 8.0 ± 0.17 × 14.5 ± 0.44 (7.5–9.0 × 13.0-17.0) mm; reproductive season, minimally July (this study)–August (Zweifel 1959, *op. cit.*) and probably much longer; and reproductive potential, multiple clutches based on maturation of both sexes at a small body size within the long activity cycle in subtropical regions of Sinaloa.

Collecting data for the CAS sample further indicated that *A. c. nigrigularis* achieves high population densities at numerous sites within a distribution area that is inhabited by no other species in the genus *Aspidoscelis*.

I thank Robert C. Drewes (CAS) for the opportunity to examine specimens in his care.

ASPIDOSCELIS LAREDOENSIS (Laredo Striped Whiptail) × ***ASPIDOSCELIS GULARIS GULARIS*** (Texas Spotted Whiptail). **REPRODUCTIVE POTENTIAL**. Clonal complex A (Walker 1987a. Texas J. Sci. 39:313–334) of diploid (Bickham et al. 1976. Herpetologica 32:395–399) parthenogenetic *Aspidoscelis laredoensis* (nomenclature based on Reeder et al. 2002. Am. Mus. Novit. 3365:1–61), derived from a single hybrid (Abuhteba et al. 2000. Can. J. Zool. 78:895–904) of *A. gularis gularis* × *A. sexlineata* (McKinney et al. 1973. Herpetologica 29:361–366), is syntopic with *A. gularis gularis* at Los Ebanos (between the town and the Rio Grande), Hidalgo County, Texas (26.2341667°N, 98.5605556°W, datum WGS84; elev. 26 m; Walker 1987b. Am. Midl. Nat. 117:319–332). On 25 May 1986, JMW, JEC, and MAP collected 3 male lizards (University of Arkansas Department of Zoology, UADZ 1948–1950) at this site characterized by the basic striped and spotted adult dorsal pattern of all-female *A. laredoensis* and a ventral pattern intermediate between this species and *A. gularis gularis*. Each of these males is a triploid hybrid resulting from a haploid sperm of *A. gularis gularis* (1n = 23) fertilizing the unreduced egg of *A. laredoensis* (2n = 46). *Aspidoscelis laredoensis* A has been identified as a participant in numerous other hybridizations. Walker et al. (1989a. J. Herpetol. 23:119–130) listed 23 hybrids (including UADZ 1948–1950) from 8 sites in Texas and 3 in México and Walker et al. (1989b. Copeia 1989:1059–1064) described the triploid karyotype of a male *A. laredoensis* × *A. gularis gularis*. Here, we detail the morphological and histological examination of a male hybrid (UADZ 1948) from Los Ebanos.

Based on Walker et al. (1989b, *op. cit.*), Taylor et al. (2001. Am. Mus. Novit. 3345:1–65), and Walker et al. (2006. Herpetol. Rev. 37:344–345), JMW described the gross reproductive morphology of the preserved hybrid. Based on Goldberg and Beaman (2003. Herpetol. Rev. 34:143), SRG histologically examined the left testis and left epididymis of the hybrid and assessed its previous reproductive functionality.

The preserved hybrid was 62 mm SVL (mass unavailable). Compared to male *A. gularis gularis* of similar size from Los Ebanos, its testes (mean dimensions of both = ca. 4 × 6 mm), epididymides, and hemipenes were of expected size and structure. Histology of the left testis indicated that the hybrid was undergoing early spermiogenesis. As reported for other teiid lizards (Lowe and Goldberg 1966. J. Morphol. 119:277–281), a circumtesticular tunic 1–3 Leydig cells thick surrounded the left testis. Clusters of metamorphosing spermatids were present and tails of spermatozoa projected into the lumina of the seminiferous tubules. Sperm were also present in the sectioned epididymis.

This *A. laredoensis* × *A. gularis gularis* hybrid would have been deemed fertile based on cytological characteristic of testes in species such as *A. tigris* (Lowe and Goldberg 1966, *op. cit.*). However, though it seemed capable of producing sperm and inseminating females of *A. laredoen*sis and *A. gularis gularis* at Los Ebanos, its ability to produce a stable haploid chromosome complement from triploid number of 69 is dubious. Nevertheless, the hybrid likely would have interfered with normal reproduction in some females of these two species should any of them have been inseminated. Taylor et al. (2001, *op. cit.*) provided indirect histological evidence that the more numerous triploid hybrid males of *A. tesselata* × *A. marmorata* (N = 12) collected at Arroyo del Macho, Chaves County, New Mexico, may have inseminated congeneric females at this site.

Collection of UADZ 1948–1950 was made under authority of Permit No. 61 issued to JEC in 1986 by the Texas Parks and Wildlife Department. Field studies at the Los Ebanos site in the Lower Rio Grande Valley National Wildlife Refuge, under the protectorate of the U.S. Fish and Wildlife Service, were conducted under Permit 21552-07-09-ms granted to JEC.

CHAMELEO RUDIS (Ruwenzori Side-striped Chameleon). **REPRODUCTION.** Few data exist on clutch size and sex ratio, and neonate size for most viviparous chameleons. Recently, many species have been described from the tropical and montane forests of East Africa (Neças et al. 2003. Trop. Zool. 16:1–12; Menegon et al. 2002. J. Herpetol. 36:51–57; Largen 1995. Trop. Zool. 8:333–339; Tilbury 1991. Trop. Zool. 4:159-165; Tilbury 1992. Trop. Zool. 5:1–9; Klaver and Bohme 1988. Bonn. Zool. Beitr. 39:381–393), and additional cryptic or semi-cryptic species have been distinguished from previously described species (Neças 1994. Herpetozoa 7[3/4]:95–108). Thus, even existing data addressing clutch characteristics may be questionable unless linked to voucher specimens that confirm species identity.

In mid-January 2007, a recently deceased gravid female chameleon, included in a shipment form Tanzania, was received from an animal dealer in Calgary. PADW identified it as *Chamaeleo rudis* (Spawls et al. 2002. A Field Guide to the Reptiles of East Africa. Academic Press, San Diego, California. 543 pp.) based on the enlarged granules on the median line of the throat extending onto the belly; no cranial horns or sail-like dorsal crest; heterogeneous body scalation with scattered large tubercles; head less than twice as long as broad; nostrils laterally directed; and body squat. Snout–vent length (SVL) and tail length were measured to the nearest 1 mm, head length (HL) and head width (HW) were measured using a Mitutoyo Digital Caliper Model 500-322 to the near-

TABLE 1. Data on 12 *Chameleo rudis* embryos; mass in grams, all other measurements in millimeters.

	Individuals	SVL	Tail	HL	HW	Mass
Females	1	30.7	24.8	9.9	6.2	0.61
	2	26.7	21.0	10.0	5.9	0.53
	3	24.7	23.0	9.6	5.8	0.47
	4	26.0	23.8	9.5	5.8	0.50
	5	26.3	24.3	9.8	5.8	0.48
	6	27.5	23.5	9.9	5.9	0.51
	mean	27.0	23.4	9.8	5.9	0.52
Males	1	26.7	21.0	10.2	5.9	0.57
	2	27.2	22.7	9.9	5.9	0.51
	3	27.0	22.3	10.1	6.2	0.46
	4	26.3	22.3	9.6	5.9	0.51
	5	27.7	22.0	10.0	6.0	0.49
	6	27.5	20.7	9.7	6.0	0.49
	mean	27.1	21.8	9.9	6.0	0.51

est 0.1 mm; each measurement was taken three times, then averaged. Measurements are: 81 mm SVL, 82 mm tail, 25.7 mm HL, 14.8 mm HW.

Twelve near full-term embryos were found *in utero*, six in each oviduct. The sex ratio was six males, six females (4.2 in one oviduct and 2.4 in the other). Gender was determined either by direct observation of at least one everted hemipenes in males (three specimens) or by observation of two circular openings into the retracted hemipenes at the lateral corners of the vent. Accuracy of the latter approach was verified by making a medial incision on the ventral side of the tail immediately posterior to the vent in two suspected males and two suspected females. Presence of a cone-shaped connective tissue sheath overlying the conical muscle, transversus penis, which surrounds the hemipene, confirmed male gender. These structures were absent in the suspected females. All embryos were measured and weighed (Table 1).

Female embryos had longer tails than male embryos (Mann Whitney U test: $P = 0.03$) but it is unknown whether this sexual dimorphism carries into adulthood with this species, however, in dwarf chameleons some ecomorphological sex-specific variation has been documented (Stuart-Fox and Moussalli 2007. J. Evol. Biol. 20:1073–1081). SVL, HL, HW, mass, ratio of tail length to SVL, and ratio of HW to HL did not differ between genders (Mann-Whitney U test: $P > 0.11$ for these 6 comparisons). However, variation in SVL for female embryos was significantly greater than variation in SVL for male embryos (Variance ratio test: F = 15.4, $P < 0.01$).

The adult female (L07.15.1) and male embryo 1 (L07.15.2; see Table 1) were deposited in the Royal Alberta Museum, Edmonton, Alberta, Canada.

CROTAPHYTUS COLLARIS (Eastern Collared Lizard). **HOMING.** Previously, I reported an instance of homing by a male collared lizard that became separated from his territory by the outflow of the Arcadia Lake Reservoir (Baird 2004. Herpetol. Rev. 35:167). In that instance, possible routes for homing to its territory were either to travel an indirect and lengthy (> 800 m**)** overland route through the territories of several other *C. collaris* males, or to swim across the outflow channel (9.5 m). On 20 June 2006, I observed another territorial *C. collaris* male, a paint-marked subject in my space-use studies, attempting to swim across the channel. This male's territory was on the north side of the channel, but because no water was released during most of May and June 2006, he made occasionally forays into the dry channel and onto its south side. The outflow was opened at 0530 h on 19 June and remained open for three days. From 1000 to 1020 h on 20 June, I made a focal observation of this male, then on the south side of the now flowing channel that separated him from his north-side territory. Throughout the entire 20-min observation, this male moved back and forth along the bank while peering across to the north side. Thirty min after the end of the focal observation, I sighted this male swimming in the midst of the outflow, presumably in an attempt to return to his territory. I followed him for 120 m as the current carried him downstream. When it became apparent that he would not reach the rocks on the other side before being swept over the end of the spillway, I waded into the water, caught the lizard, and returned him to his territory. Upon capture, the male's lungs were completely inflated, allowing floatation. This observation implies that my 2002 report of homing also involved swimming across the flowing channel, and that the drive to home is strong enough in territorial *C. collaris* males that fast-flowing water does not appear to be a deterrent. The spillway at the Arcadia Lake Reservoir is human constructed, but *C. collaris* may face similar flowing aquatic barriers during flash flooding events.

This study was conducted under Oklahoma Department Wildlife Conservation permit 4097 to Troy A. Baird.

HOPLOCERCUS SPINOSUS (NCN). **ENDOPARASITES.** *Hoplocercus spinosus* is a poorly known lizard distributed from Mato Grosso and Mato Grosso do Sul States, Brazil to adjacent Bolivia (Wiens and Etheridge 2003. Herpetologica 59:375–398). To our knowledge, no parasite records were published for *H. spinosus*. Hence, we report the nematode, *Cruzia rudolphii*, infecting *H. spinosus.*

Five adult *H. spinosus* (mean = 80.4 mm SVL, SD = 12.3 mm) deposited in the Coleção Zoológica de Referência, Laboratory of Zoology, *Campus* of Corumbá, Universidade Federal de Mato Grosso do Sul (UFMS; CEUCH 2888, 2892, 3374, 3375, and 3460) were examined for endoparasites. Lizards were captured in No-

vember 2003 and February 2004 in pitfall traps with drift fences in a remnant patch of Cerradão (savanna-like vegetation) of Dois Irmãos do Buriti and Terenos (55.30°W, 20.50°S, datum: WGS84) between the municipality of Aquidauna and Campo Grande, Mato Grosso do Sul State, Brazil. Endoparasites were cleared in phenol, identified and deposited in the Coleção Helmintológica do Instituto de Biociências da Unesp de Botucatu as *Cruzia rudolphii* (CHIBB 1052). Three adult females of *C. rudolphii* were recovered and the observed prevalence (infected lizards / examined lizards × 100) was 20%.

Species of *Cruzia* have been reported in mammals (Quintão e Silva and Costa 1999. J. Wildl. Dis. 35:371–374) and reptiles (Vicente et al. 1993. Rev. Bras. Zool. 10:1–183). *Cruzia rudolphii* was described from the colubrid snake *Erythrolamprus aesculapii* in southeastern Brazil (Ruiz [1947] in Vicente et al. 1993, *op. cit.*). *Hoplocercus spinosus* represents a new host record for *C. rudolphii* and Mato Grosso do Sul, Brazil is a new locality for *C. rudolphii*.

We thank Marc P. Hayes for comments in the manuscript. This study had financial support by FAPESP (processes 04/03628-1; 06/59692-5) and RWA thanks CAPES for a grant.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **MORTALITY.** Literature on horned lizards (*Phrynosoma*) reveals that horn length is an anti-predator device whereby individuals with larger horns are less susceptible to mortality from predation (Young et al. 2004. Science 304:65). Behaviors where horned lizards thrust their heads back to inflict puncture wounds into would-be predators support this idea (Brodie et al. 2004. Science 306:230b; Sherbrooke 2003. Introduction to Horned Lizards of North America. University of California Press, Berkeley. 177 pp.). However, elongated cranial horns have not been implicated as contributing to mortality. We report mortality of *Phrynosoma cornutum* resulting from entrapment of the horns in a hardware cloth fence.

On 15 April 2007, a young adult female *P. cornutum* (ca. 77 mm SVL) was found dead in a hardware cloth fence in the San Simon Valley, Cochise County, Arizona (31.93°N, 109.08°W; elev. 1330 m). The lizard was found entrapped in the area of overlap where two sections of 6.4-mm mesh wire hardware cloth had been joined to form a single fence (Fig. 1). The 60-cm tall fence was riveted at the top through a 15-cm tall strip of sheet metal, and at the ground the fence was buried in the soil. The lizard was aligned nearly vertically about midway up the 45 cm of exposed fence, ca. 10 cm from the edge of the overlap, where a small gap between

FIG. 1. Texas Horned Lizard, *Phrynosoma cornutum*, entrapped in overlapping sheets of hardware cloth used in a fence in Cochise County, Arizona.

the sheets of hardware cloth likely allowed entry. The lizard's occipital horns were protruding from and enmeshed in the hardware cloth. The body was completely desiccated but showed no other decay and was not noticeably faded. The only damage visible was two holes ca. 2 mm in diameter bored dorsally though the midway of tail and ventrally just caudal to the cloaca, likely the result of scavenging insects.

We suspect that the lizard was unable to escape entrapment of its horns in the mesh and later died. Entrapment or entanglement in anthropogenic materials has been recorded for many animal species, in some cases in surprising numbers (e.g., Barton and Kincead 2005. J. Soil Water Cons. 60:33A–35A; Loegering 1997. Wilson Bull. 109:353–355), though the cause of mortality we report is probably rare. Because of the potential for entrapment, however, we suggest caution in the use of hardware cloth in areas where horned lizards of conservation concern occur, such as in the range of the Flat-tailed Horned Lizard, *P. mcallii*. Thoroughly securing the overlapping ends of fencing would likely alleviate the potential for such mortality.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **PREDATION.** *Phrynosoma cornutum* has a broad distribution in North America (Price 1990. Cat. Amer. Amphib. Rept. 469.1–7; Sherbrooke 2003. Introduction to Horned Lizards. University of California Press, Berkeley 178 pp.). Knowlton (1942. Copeia 1942:186), Miller (1948. Copeia 1948:67), and Sherbrooke (2003, *op. cit*.) indicate that the vertebrate predators of *P. cornutum* include the Greater Roadrunner (*Geococcx californianus)*, Red-shouldered Hawk (*Buteo lineatus*), Chihuahuan Raven (*Corvus cryptoleucus)*, and the Western Diamond-backed Rattlesnake (*Crotalus atrox*). Prey decapitation, a important feeding tactic used by some raptorial birds to minimize risk from dangerous prey, has not been reported to be used on horned lizards. Hence, we report an observation of prey decapitation by Swainson's Hawk (*Buteo swainsoni*) on *P. cornutum*.

Our observations were made between 15 June and 15 August 2006 during research on the reproductive biology of *B. swainsoni* in the Reserva de la Biosfera de Janos (31.1854528°N, 108.9469917°W and 31.1909583°N, 108.9394694°W, datum: NAD27; elev. 1350–1400 m), in Janos, Chihuahua, México. Our study was conducted in open desert scrubs dominated by Honey Mesquite (*Prosopis glandulosa*), Viscid Acacia (*Acacia neovernicosa or A.constricta*), and Catclaw Mimosa (*Mimosa biunicifera*). We analyzed the regurgitated pellets and prey remains of 19 occupied *B. swainsoni* nests with young, all of which were in *P. glandulosa* trees. We found the remains of *P. cornutum* in 8 nests, all of which were heads. To estimate body size, we recorded the mean distance between the distal ends of temporal (squamosal bone) horns. For the 14 *P. cornutum* heads collected, temporal horn distance (D_{th}) ranged from 1.72 mm to 2.14 mm. Based on a preliminary linear SVL–temporal horn distance regression (SVL = 1.978 + 3.244[D_{th}]) constructed from 34 *P. cornutum* in the herpetological collection of the Universidad Autónoma de Nuevo León, the heads all belonged to adults estimated to range in size from 75 mm to 89 mm. No other remains from these lizards were found in the nests, suggesting that the lizards were either dismembered and fed to juveniles or consumed by adult hawks.

Buteo swainsoni, with a broad distribution throughout much of North and South America (Clements 2000. Birds of the World: A Checklist. Ibis Publishing Co., Vista, California. 867 pp.**)**, has a diet that includes horned lizards (Bednarz 1988. The Condor 90:311–323). Bednarz (*op. cit*.) notes that based on biomass, *B. swainsoni* diet included 6.2% *P. texanus (= cornutum*). Our observations imply that *B. swainsoni* may decapitate *P. cornutum* prior to eating them.

Submitted by **DAVID LAZCANO, BLANCA IDALIA GONZALEZ.-.GARZA NERYEDA CRUZ.-.MALDONADO,** and **JOSE IGNACIO GONZALEZ.-.ROJAS,** Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado, Postal - 513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México (e-mail [DL]: dvlazcano@hotmail.com).

PHRYNOSOMA MCALLII (Flat-tailed Horned Lizard). **RAIN HARVESTING**. Three species of *Phrynosoma* (*P. cornutum*, *P. modestum*, and *P. platyrhinos*) exhibit a behavior termed rain harvesting (Sherbrooke 2003. Introduction to Horned Lizards of North America. University of California Press, Berkeley, California. 178 pp.). In this stylized behavior, occurring during infrequent desert rains, a lizard elevates its venter from the substrate and positions its dorsal surface so that it intercepts rain which then moves by capillary action and bulk flow to the head and mouth where it is imbibed. We tested for this behavior in a fourth species of horned lizard, *P. mcallii*, because it lives in the most arid habitat of any horned lizard. Moreover, *P. mcallii* has never been observed to drink standing water in captivity and is assumed to procure moisture from its food (Mayhew 1968. *In* G. W. Brown, Jr. [ed.], Desert Biology: Special Topics on the Physical and Biological Aspects of Arid Regions, Volume 1, pp. 195–356. Academic Press, New York). Here, we provide evidence that *P. mcallii* engages in rain harvesting.

We equipped 64 lizards with radio-telemeters in the East Mesa area of the Imperial Valley (32.8222222°N, 115.2527778°W, datum: NAD83; elev. 10–15 m), California during the summer and fall of 2004. This area is in the Colorado Desert subsection of the Sonoran Desert. Large Creosote (*Larrea tridentata*) and sandy substrate characterizes the habitat. To test whether *P. mcallii* exhibits the stylized rain-harvesting posture, we opportunistically sprayed 5 relocated lizards with a heavy mist from a spray bottle. Two of these lizards exhibited behaviors consistent with rain harvesting. One lizard, from which we had just removed the transmitter harness, moved under a small, leafless bush where we sprayed it with water. This lizard promptly elevated its venter from the substrate, angled its dorsum to slope downward toward its head, and expanded its dorsum. Water sprayed on the lizard flowed toward the head and rhythmic swallowing motions followed. The second responsive lizard exhibited a less prompt and stylized response. This lizard walked under a small, leafless shrub that did little to obstruct our view or the sprayed water. When the lizard was sprayed, it remained off the substrate with its venter elevated and expanded the dorsum slightly. This lizard was standing on a slope which effectively angled its dorsum downward. Water collected on its dorsum and collected near the mouth, where it was swallowed. The transmitter was left on this individual. These observations parallel those described for the three species of *Phrynosoma* known to harvest rain; namely, venter elevated from the substrate, dorsum spread, and dorsum sloped toward head.

The Bureau of Land Management (particularly Daniel Steward, Lynette Elser, and Chris Knauf at the El Centro, California, Field Office), Department of the Navy, Bureau of Reclamation, and U.S. Fish and Wildlife Service provided support for this project. The California Department of Fish and Game approved a scientific collecting permit No. SC-007201. Erin Dreyfuss, Christi Duncan, Brent Eastty, Angela Hyder, Darren Kelly, Justin Nobel, and Amanda Trahan assisted with field work.

PHRYNOSOMA SOLARE (Regal Horned Lizard). ***CROTALUS* ENVENOMATION**. On 14 September 2006, we studied the behavioral responses of an adult male *Phrynosoma solare* (93 mm SVL, 50.5 g) to a venomous ophidian predator, the Western Dia-

mondback Rattlesnake (*Crotalus atrox*; Vorhies 1948. Copeia 1948:302–303). The capture and experimental trial site of the *P. solare* was near a small volcanic hill in Altar Valley, Pima Co., Arizona, USA (32.0365278°N, 111.3962778°W, datum: WGS84; elev. 822 m). To conduct these trials, we released the lizard at its capture site after 5 days in captivity. We had collected the *C. atrox* (82 cm SVL, 8 cm tail, 385 g) in Avra Valley west of the Tucson Mountains, Pima Co. Tucson, Arizona (32.1859722°N, 111.0996944°W; elev. 792 m). For the trials, we placed the snake in a 46-cm long, 3.5-cm diameter clear plastic tube. The snake's head and forebody extended 15-cm from one end of the tube, while the tail extended from the opposite end. The experimenter held the posterior end of the tubed snake during presentations of its foreparts to the lizard. During trial encounters with this lizard, the lizard was unexpectedly struck by the snake on the third presentation of the snake. Before envenomation, the lizard had failed to exhibit antipredator escape-running or body-flip behaviors, but did tilt its body laterally toward the snake, raise its horns, and was contacted by the snake's head in all three encounters (Sherbrooke and May, unpubl. data). Though episodes of rattlesnake predation on horned lizards, including full and partial ingestions (successful or unsuccessful), have been reported (Beavers 1976. Southwest. Nat. 20:503–515; Funk 1965. Herpetologica 21:15–17; Sherbrooke 2003. Introduction to Horned Lizards of North America, University of California Press, Berkeley. 178 pp.), no accounts exist of the effects of *Crotalus* envenomation on horned lizards.

At 0928 h MST, a bite strike resulted in one fang penetrating the lizard's dorsal skin 11 mm anterior to the left hind leg and 8 mm above the lateral fringe scales. A small drop of blood immediately oozed from the wound, but did not spread. By 0934 h, a clear fluid (ca. 0.5 ml) seeped from the wound onto the experimenter's hand, and the lizard seemed to be experiencing difficulty moving its limbs. By 0950 h, the lizard was lethargic, with continuing fluid loss and a lightening of its body color; and by 1004 h, a pinkish fluid (presumably blood and lymph) was exuding from both nostrils. The lizard now appeared dead and was unresponsive to handling. Its head remained in a strong horns-raised posture (90° angle; Sherbrooke 1987. Southwest. Nat. 32:512–515).

The lizard was frozen and later formalin/ethanol preserved and is deposited in the Herpetology Collection of the University of Arizona, Tucson (UAZ 56621). Scientific collecting permit (SP651312) to WCS was provided by the Arizona Department of Game and Fish.

PHYMATURUS ANTOFAGASTENSIS (NCN). **DIET**. *Phymaturus antofagastensis* is a viviparous lizard inhabiting the high plains (altiplano) of the Andean Mountains in central and northern Argentina (Cabrera and Willink 1980. Biogeografía de América Latina. Washington, DC. 109 pp.). This species is sexually dimorphic and females exhibit biennial reproduction (Boretto and Ibargüengoytía 2006. Amphibia-Reptilia 27:25–36). Its conservation status is ambiguous as it is defined as a species for which "insufficient knowledge" exists (Lavilla et al. 2000. Categorización de los Anfibios y Reptiles de la República Argentina. Asoc. Herpetol. Arg., San Miguel de Tucumán, Argentina, 97 pp.). The genus *Phymaturus* is considered herbivorous (Espinoza et al. 2004. Proc. Nat. Acad. Sci. 101:16819–16824), but we provide preliminary data indicating that *P. antofagastensis* can also be frugivorous.

Our observations were based on data from 10 *P. antofagastensis* collected during January 2005 in Valle de Chaschuil, Catamarca Province, Argentina (27.72°S, 68.15°W, datum: WGS84; elev. 4200 m). Soil is sandy and rocky; the vegetation is shrub-steppe. The climate is cold and semiarid with broad diel thermal range and intense solar radiation (Boretto and Ibargüengoytía 2006, *op. cit.*. The lizards were taken to the laboratory, where they defecated; we examined their feces with a magnifying lens. We analyze a total of 10 feces, counting the number of seeds of fruits present. We estimated the percent volume of non-seed vegetable matter as a function of total fecal volume.

We found no arthropod remains. Only plant material representing the seeds of *Lycium chanar* and *Ephedra multiflora*, and non-seed material representing leaves or fruit tissue of *L. chanar* and *E. multiflora* were observed. The fruits of *L. chanar* and *E. multiflora* in the feces were in various stages of digestion. We counted a total of 488 seeds. Mean number of *L. chanar* seeds in each fecal pellet was 45.7 (SD = 30.9, range: 0–103); mean number of *E. multiflora* seed was 3.1 (SD = 5.3, range: 0–16). Mean percent volume of non-seed vegetative material was 56.4 (SD = 7.1, range: 45–65).

Our results indicate that the fruits of *L. chanar* and *E. multiflora* represent an important source of nutrition for *P. antofagastensis*. Other Andean lizards (e.g., *Pristidactylus scapulatus* [Acosta et al. 2004. Herpetol. Rev. 35:171–172], *Liolaemus ruibali* [Villavicencio et al. 2005. Multequina: Latin American J. Nat. Res. 14:47–52], and *Homonota andicola* [Blanco and Acosta 2005. VI Congreso Argentino de Herpetología. 70 pp.]) also consume *Lycium* and *Ephedra* fruits. Fruits represent food with easily usable energy wealth for many squamates (Pough et al. 2001. Herpetology. Prentice Hall, New Jersey. 612 pp.). *Phymaturus antofagastensis* also has the potential to behave as a seed disperser. Given the observed frugivory, plant-lizard interactions involving *P. antofagastensis* and fruit-producing shrubs deserve investigation. We thank M. Hayes for comments and suggestions.

PLESTIODON FASCIATUS **(**Common Five-lined Skink**). ESCAPE BEHAVIOR.** *Plestiodon fasciatus* is a small, diurnal skink that occurs throughout most of the eastern half of the United States (Mount 1996. The Reptiles and Amphibians of Alabama. University of Alabama Press. Tuscaloosa, Alabama). Between 1400 and 1500 h on 27 June 2006, during a visit to Glen Burnie, Maryland (39.16°N, 76.61°W), I witnessed what appeared to be a distinctive escape maneuver by *P. fasciatus*. Skinks (N = 7) basking on a

wooden railing along a path through a woodland fled for cover under a log when I approached. When I pursued the first skink by overturning the log under which it had taken cover, a large number of ants were found swarming beneath it. The same situation arose with another four *P. fasciatus*, each found along the same path. These lizards were also beneath cover objects (debris and leaf litter) housing ants. All five lizards observed appeared to be sub-adults,between ca. 50 and 65 mm SVL. When 25 nearby cover objects—similar to those used by skinks—were randomly sampled, only four housed ants beneath them, and (excepting the five mentioned above) only one had a high density of ants similar to that observed under cover objects utilized for escape by *P. fasciatus*.

Once established, *P. fasciatus* appear to have stable home ranges (Fitch 1954. Univ. Kansas Publ. Mus. Nat. Hist. 8:1–156). Consequently, individuals should be familiar with most possible escape routes within their home range. My observations imply that *P. fasciatus* preferentially flee to ant-associated cover objects during escape attempts. To my knowledge, this behavior is undocumented among lizards. Predators that pursue skinks under cover objects with ants may be deterred by the agitated ants. The smooth scales and associated osteoderms of *Plestiodon* would protect them from ants. Further observations are needed to determine how widespread this behavior is and to test the hypothesis of whether *P. fasciatus* actually exploit ant colonies within their home range for defense.

I thank Laurie J. Vitt, Mark O'Shea, Graeme Ruxton and Maggie Reilly for their comments on the text.

PLESTIODON MULTIVIRGATUS EPIPLEUROTUS (Variable Skink). **MATING.** Little is known about reproduction in *Plestiodon multivirgatus epipleurotus* (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque. 431 pp.). Everett (1971. J. Herpetol. 5:189–190) provided details of courtship and mating among captive specimens (two males and one female) from Lamb County, Texas, but mating has not been observed in the field. Hence, we report a field observation of mating in a high altitude population of *P. m. epipleurotus* near the southwestern limit of this taxon's range (Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix. 150 pp.).

At ca. 1300 h on 2 May 2007, CBG discovered a mating pair of *P. m. epipleurotus* in a small depression under a piece of particleboard in Fry Canyon, just west of US Hwy 89A, ca. 20 km SSW Flagstaff, Coconino Co., Arizona (35.0637833°N, 111.73315ºW, datum: WGS84; 2003 m elev.). Ambient temperature was 18.3°C and the sky was mostly overcast. A considerably smaller male (ca. 50 mm SVL) was in copula with a larger female (ca. 70 mm SVL), biting the left side of her neck and oriented on her left side. The lizards were apparently not disturbed, as they remained in copula after they were uncovered until the board was quickly (<10 sec) returned to its original position.

Timing of this mating event appears consistent with the seasonal appearance of eggs and hatchlings among other high-elevation populations of this taxon. Gehlbach (1956. Trans. Kansas Acad. Sci. 59:364–373) found hatchlings on 29 July at 2060 m elevation in McKinley Co., New Mexico. He also discovered a clutch of eggs on 28 June and hatchlings on 29 July and 17 August in the Zuni Mountains (2215 m), Cibola Co., New Mexico (Gehlbach 1965. Proc. U.S. Nat. Mus. 116:243–332). Similarly, Maslin (1957. Herpetologica 13:87–90) reported 4 egg clutches found 7 June on the Upper Colorado Plateau (2555 m) in San Juan Co., Utah. Our observation of an early May mating implies that egg development likely requires 5–7 weeks before the onset of oviposition.

We thank Andrew Holycross for suggestions and Kenneth Krysko for key literature.

PLICA PLICA (NCN). **REPRODUCTION.** The scansorial arboreal tropidurid *Plica plica* is widespread in Amazonia (Vitt 1990. Can. J. Zool. 69:504–511). Reproduction in *P. plica* has been studied (Vitt, *op. cit.*), but data are lacking on the incubation interval. Here, we provide preliminary data on the incubation interval for *P. plica*.

On 4 March 2005, the day after the capture of a gravid female (145 mm SVL, 80 g) at Floresta Nacional de Carajás, Estado do Pará, Brazil (06.30°S, 50.20°W; elev. 500 m), she laid a clutch of five eggs in laboratory. The clutch was maintained in a plastic tub with moist sand and litter, at a constant 24°C. Placed near a glass window, the tub received indirect ambient light throughout incubation, but light regime was not rigorously controlled. One egg spoiled the week after oviposition and was discarded. The remaining four eggs hatched in 122 days (on 4 July 2005). Hatching from the first three eggs was almost simultaneous (at 1340, 1345 and 1346 h), but the fourth hatchling emerged almost two hours later (1538 h). Table 1 provides measurements of hatchlings. Simultaneous hatching of the first 3 eggs agrees with Vitt (*op. cit.*), who described synchronous hatching of *P. plica* eggs after disturbance.

Compahia Vale do Rio Doce supported this work.

POLYCHRUS MARMORATUS (NCN)**. MATING.** The neotropical genus *Polychrus* contains five medium-sized (120–150 mm) diurnal arboreal species (Peters and Orejas-Miranda 1986. Catalogue of Neotropical Squamata. Part II, Lizards and Amphisbaenians. Revised ed. Smithsonian Institution, Washington, DC. 293 pp.). Vitt and Lacher (1981. Herpetologica 37:53–63) described mating in *P. acutirostris*, and Beebe recorded but did not describe mating in *P. marmoratus* (Beebe 1944. Zoologica 29:195–216). Here we describe mating by *P. marmoratus* in eastern Brazilian Amazônia.

Our observations were made at Floresta Nacional de Carajás (06.0569444°S, 50.145°W, datum: SAD69, elev. 500 m). Lizards were captured on the morning of 23 December 2004 in low vegetation along a road in continuous forest. They were placed in a transparent plastic tub (25 × 35 × 15 cm) in a room under artificial (fluorescent) light where the temperature was a constant 24°C (slightly below field temperature at the time of capture). Observations began at 1800 h the same day, when we found the male riding the female's back while biting her neck and trying to penetrate her cloaca. Copulation began at 1820 h and lasted more than an hour. The male made rhythmic movements with his pelvis until 1930 h, and during all this time, a white secretion was visible on his vent. After copulation, the male disengaged from the female, gaped and made atypically fast respiratory movements. The male remained on female's back until 2315 h. The female remained passive througout all the process and no interactions were observed after separation.

Mating in *P. marmoratus* is similar to mating in *P. acutirostris*. However, prominent differences exist, including the longer copulatory period and the absence of aggressive behaviour on the part of the female post-copulation; however, these differences may be artifacts of the captivity that only field observations can elucidate. Vitt ánd Lacher (*op. cit.*) observed female aggressive behavior toward the male before copulation and concluded that females select their mates. Our observations began after mating had begun, preventing us assessing pre-copulatory behavior.

RHACODACTYLUS AURICULATUS (Gargoyle Gecko). **SAP FEEDING.** *Rhacodactylus auriculatus* is a large (125 mm maximum SVL) diplodactylid gecko endemic to mainland New Caledonia (Bauer and Sadlier 2000. The Herpetofauna of New Caledonia. SSAR, Ithaca, New York. 322 pp.). Between 28 July and 4 August 2004, an adult female (122.8 mm SVL, 36.0 g) that was being tracked by radiotelemetry in Parc Provincial de la Rivière Bleue, Province Sud (22.1000°S, 166.6444444°E, datum: WGS84; elev. 225 m), was seen licking sap from a *Cunonia macrophylla* tree on three separate nights. During daylight hours, she perched on vegetation within a radius of < 3 m from the tree, returning within 2 h of sunset to feed on a wound on the tree trunk. During video-documentation lasting 69 min 56 sec, this female licked the sap 662 times (Fig. 1). Licking was intermittent; several consecutive licks were followed by pauses of up to 1 min 41 sec.

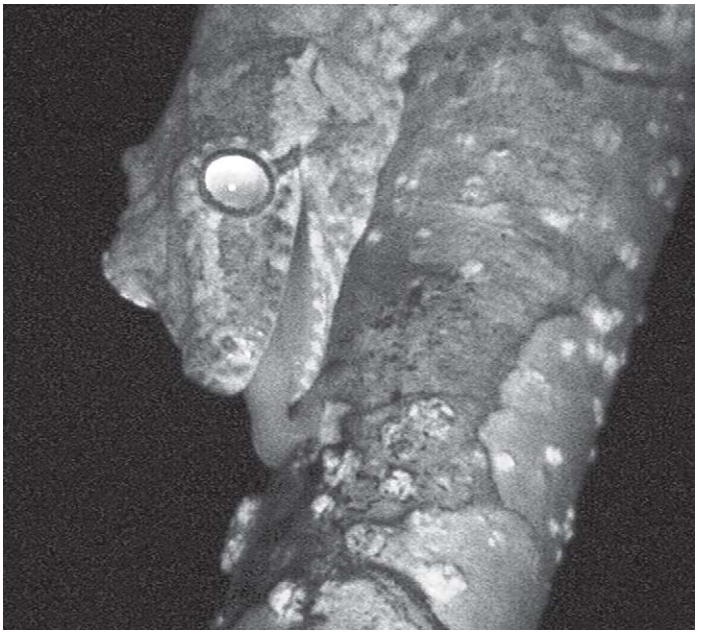

FIG. 1. Infrared video still of *Rhacodactylus auriculatus* feeding on the sap of *Cunonia macrophylla.*

Rhacodactylus auriculatus has been reported to feed on flowers and flower parts since the species was first described. Bavay (1869. Mém. Soc. Linn. Normandie 15:1–37) observed *R. auriculatus* feeding on flowers of *Geissois* spp., another member of the Cunoniaceae. Flower consumption by *R. auriculatus* has further been confirmed by the recovery of anthers and stamens referable to either the family Cunoniaceae or Myrtaceae from the stomach of a preserved specimen (Bauer and Sadlier 1994. Russ. J. Herpetol. 1:108–113) and Bauer and Sadlier (2001. Amphib. Rept. Conserv. 2:24–29) reported *R. auriculatus* activity on a flowering *Geissois* sp., though ingestion of plant material was not observed. Our observation constitutes the first field-based report of *R. auriculatus* feeding on sap and further supports the regular dietary use of plants of the Cunoniaceae by *R. auriculatus*.

Many gecko species (chiefly insular forms) have been implicated in frugivory or nectivory (Whitaker 1987. New Zeal. J. Bot. 25:315–328; Cooper and Vitt 2002. J. Zool. London 257:487–517), however field observations of feeding on sap has previously been recorded only for three species of the genus *Gehyra* (Couper et al. 1995. Mem. Qld. Mus. 38:396; Dell 1985. W. Aust. Nat. 16:69–70; Letnic and Madden 1998. W. Aust. Nat. 21:207–208). Because they are rapidly absorbed by the digestive tract, nectar and sap are difficult to identify in gut contents retrieved from preserved specimens. Flower parts consumed incidentally to high-energy nectar can indicate nectivory (Bauer and Sadlier 1994, *op. cit.*), but sap feeding is virtually undetectable unless a feeding event is actually observed.

Submitted by **JOSHUA P. SNYDER** (e-mail: joshua.p.snyder@villanova.edu), **LESLIE A. SNYDER**, and **AARON M. BAUER**, Department of Biology, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085, USA.

SCELOPORUS OLIVACEUS (Texas Spiny Lizard). **PREDATION.** *Sceloporus olivaceus* occurs from the Texas-Oklahoma border into México, extending to southern Tamaulipas, all through Nuevo León, southeastern Coahuila, northeast San Luis Potosí, and a tiny portion of northern Veracruz (Kennedy 1973. Cat. Amer. Amphib. Rept 143.1–143.4; Smith 1979. Handbook of Lizards of the United States and Canada. Comstock Publishing Associates, Ithaca, New York. 557 pp; Köhler and Heimes 2002. Stachelleguane. Herpeton, Offenbach, Bundesrepublik, Deutschland. 174 pp.). Several snake predators of *S. olivaceus* are reported, including *Masticophis flagellum*, *Hypsiglena ochrorhyncha texana*, *Crotalus lepidus lepidus*, and *Sistrurus catenatus* (Strecker 1927. Contr. Baylor Univ. Mus. [10]:1–14; Werler 1951. Zoologica 36:37–48; Wright and Wright 1957. Handbook of the Snakes of the United of the United States and Canada. Cornell University Press, Ithaca, New York. 564 pp.; Greene and Oliver 1965. Herpetologica 21:225–228), but *Imantodes cenchoa* is not among them. Hence, here we report an observation of *I. cenchoa* predation on *S. olivaceus*.

At 2343 h on 16 July 2006 during a collecting trip through the municipality of Aldama (state of Tamaulipas), we found a DOR adult female *I. cenchoa* (480 mm SVL, 223 mm TL, 19.81 g) as we were road-collecting at 8 km E of Aldama-Barra de Tordo (22.9414194°N, 99.9954°W, datum: NAD27; elev. 141 m). As we were preserving the specimen, we extracted a juvenile *Sceloporus olivaceus* (37 mm SVL, 65 mm TL, 1.94 g) from an expanded loop in the body mid-section. This snake species had been repeatedly found on this road in previous years. The area of Barra del Tordo is undergoing intensive human development, which has greatly increased the number of DOR animals encountered.

Imantodes cenchoa, which occurs at low to moderate elevations in Mexico from Chiapas on the Pacific slope to Tamaulipas on the Atlantic slope (Lee 1996. The Amphibians and Reptiles of the Yucatan Peninsula. Comstock Publishing Associates, Cornell University Press, Ithaca, New York. 500 pp.), is documented to consume lizards and frogs. Myers (1982. Amer. Mus. Novit. 2738:1–50) reported that anoles make up most of its diet, and Landy et al. (1966. J. Ohio Herpetol. Soc. 5:93–101) found an unidentifed *Anolis* sp. and reptile eggs in the stomach of one individual. Specific reports include *Anolis capito* and *A. uniformis* (Stuart 1948. Misc. Publ. Zool. Univ. Michigan [91]:1–31); *A. marianrum* (Gutierrez and Arredondo-S. 2005. Herpetol. Review.36:324); and juvenile *Basiliscus vittatus* (Lee, *op. cit.*). However, ours is the first report of *S. olivaceus* as prey.

The specimens of *S. olivaceus* (UANL 6831) and *I. cenchoa* (UANL 6830) were deposited in the herpetological collection of the Universidad Autónoma de Nuevo Leon. Research and collecting were conducted under the authority of SEMARNAT scientific research permits OFICIO NÚM/SGPA/DGVS/00800 issued to DL.

STENOCERCUS CADUCUS (NCN). **REPRODUCTION.** Data on reproduction in *Stenocercus caducus* are scarce, and little is known about its biology in Paraguay. Cei (1993. Mus. Reg. Sci. Nat. Torino Monogr. 14:1–949) pointed out that few data exist on its reproductive activity. Clutch size has been reported in related species, such as *S. azureus* (Carreira and Baletta 2004. Herpetol. Rev. 35:270; Torres-Carvajal 2004. Herpetol. Rev. 35:172), but the nesting habits of *S. caducus* are unreported. Here, we provide preliminary observations on nesting in *S. caducus*.

At 1640–1700 h on 15 November 2006, we found a female *S. caducus* laying eggs along a forest path at Kangüery Biological Station (27.5126944°S, 55.7852222°W, datum: WGS84; elev. 158 m), inside San Rafael National Park. The female was laying the eggs in a small burrow (3–4 cm depth and 4–5 cm width) made in the earth underground, covered with leaf litter. The shape of the nesting burrow was a simple round hole, and the egg chamber was equal to or slightly small than the opening. Two eggs were deposited with an interval of ca. 10 min between them. The just-laid eggs were pale grey with white longitudinal stripes; after less than 10 sec, the eggs turned completely white, the stripes disappearing. Egg shape also changed, because just-laid eggs were bilaterally symmetrical, becoming ovoid as they dried in contact with air. We could not obtain precise egg measurements because eggs were not removed from the nest, but we estimated that they averaged 23 mm in major axis diameter. The female was 67.2 mm of SVL and 142.0 mm total length. Egg major axis diameter was 34% of the female's SVL. Measurements were taken once she finished laying eggs, and she was subsequently released at the same place.

While the female laid eggs, she was vulnerable to predator attack; however, she appeared highly cryptic on the leaf litter background. Only her hind limbs and posterior body were inside the small burrow; the rest of the body, including a large portion of the long tail, was exposed. The next day, we re-examined the nest location, and found it covered with soil and leaf litter; we could see no obvious evidence of the nest made the day before.

We thank A. A. Yanosky, J. L. Cartes, P. Smith, and M. Hayes for suggestions on the manuscript. This work was done within the framework of the Biological Monitoring of San Rafael project, supported by the Forestry Bureau, Council of Agriculture (Taiwan Government) through BirdLife International.

TROPIDURUS HISPIDUS (NCN). **HATCHLING SIZE.** *Tropidurus hispidus* has a broad distribution from central-eastern and northeastern Brazil to Venezuela (Rodrigues 1987. Arq. Zool. 31:105–230; Rodrigues 1988. *In* Heyer and Vanzolini [eds.], Proceedings of a Workshop on Neotropical Distribution Patterns, pp.

305–315. Academia Brasileira de Ciências, Rio de Janeiro, Brazil). Data are available on clutch size (Vitt 1983. Copeia 1983:131–141), but information on hatchling size is lacking. Here, we provide preliminary data on hatchling size for *T. hispidus*.

At 0820 h on 8 June 2005, CMCAL and TBGC collected 8 eggs of *T. hispidus* at the Parque Estadual das Dunas do Natal (05.8135278°S, 35.1920278°W, datum: WGS84; elev. 72 m), Natal City, Estado do Rio Grande do Norte, Brazil. Located within Atlantic Forest Domain, the nest site, a small terrestrial cavity (5 cm diameter × 3 cm deep) covered with herbaceous and shrubby vegetation (notably *Anthurium affine*, *Aechmea aquilega*, and *Krameria tomentosa*), was encountered during a transect survey. On 4 April 2007 at 0910 h, EMXF collected one egg (1109 mm^3, 0.68 g) of this species, next to DBEZ - Departamento de Botânica, Ecologia e Zoologia (Department of Botany, Ecology and Zoology) at the Campus of Universidade Federal do Rio Grande do Norte – UFRN (05.8426667°S, 35.2018611°W; elev. 69 m), Natal City. The collection location of this egg was a garden area surrounded by a forest patch. The single egg was found in soil beneath sparse leaf litter (< 1 cm deep). Eggs from each collection date were placed in a terrarium (20 × 12 × 20 cm) in a sand substrate, and maintained at the Laboratório de Herpetologia (Departamento de Botânica, Ecologia e Zoologia/UFRN). We placed the terrarium next to a window protected from direct solar radiation, but we made no efforts to otherwise control light or temperature; incubation occurred under ambient conditions. In Natal City, ambient temperatures during the June–July incubation interval for the first clutch varied from 22.0°C to 30.0°C, whereas ambient temperatures during the brief April incubation of the second single egg varied from 24.0°C to 34.0°C.

On 12 July 2005, about five weeks after the first clutch was found, juveniles began to emerge; on 8 April 2007, four days later the single egg was found, the juvenile emerged. Body measurements were taken immediately upon hatching, and each individual was sexed following euthanization (Table 1). Coefficients of variation (CV) for data among all hatchlings were quite low (< 0.05) except for mass (CV = 0.25). Tail length/body length ratio differed significantly between males (mean = 1.70 ± 0.04 mm; N = 4) and females (mean = 1.59 ± 0.04 mm; N = 5; Mann-Whitney U test: $P = 0.0143$).

TABLE 1. Data on nine *Tropidurus hispidus* hatched in the Laboratory (Estado do Rio Grande do Norte, Natal City, Brazil). Individuals 1–8 were from one clutch; individual 9 was from a second clutch. Snout–vent length (SVL), tail length (Tail), head length (HL), head width (HW) measurements are in millimeters; mass is in grams.

	Morphological Variables				
Individual	SVL	Tail	HL	HW	Mass
1 (Female)	28.2	45.7	9.4	6.5	0.58
2 (Female)	27.7	43.5	8.8	6.1	0.52
3 (Male)	27.6	48.9	9.4	6.4	0.59
4 (Male)	28.7	48.6	9.6	6.6	0.74
5 (Male)	28.6	48.3	9.2	6.1	0.55
6 (Male)	28.4	47.5	9.2	6.3	0.63
7 (Female)	27.2	43.3	9.0	5.7	0.37
8 (Female)	27.6	45.7	8.8	6.0	0.35
9 (Female)	27.6	42.7	9.3	6.6	0.40
Mean	28.0	46.0	9.2	6.3	0.53
SD	0.53	2.4	0.28	0.30	0.13

Mean body size of nine *T. hispidus* hatchlings is similar to that observed by Vitt (*op. cit.*) for individuals hatched in the laboratory (mean = 27.8 ± 0.45 mm SVL; N = 5), but their average mass is somewhat less than that recorded by Vitt (*op. cit.*; mean = 0.74 ± 0.09 g).

The *T. hispidus* (CHBEZ 1167–1174; 1715) were deposited in the herpetological collection of Universidade Federal do Rio Grande do Norte, Natal City. We thank two anonymous reviewers for helpful comments. The Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) supported LBR with a research grant (Process 141993/2006-5).

VARANUS KOMODOENSIS (Komodo Dragon). **OCCURRENCE.** *Varanus komodoensis* is a large monitor endemic to the Lesser Sunda region of southeastern Indonesia. Over the last 30 years, extant populations of *V. komodoensis* have been recorded from six islands (Auffenberg 1981. The Behavioral Ecology of the Komodo Monitor. Univ. Press of Florida, Gainesville, Florida. 406 pp.), five of which occur within Komodo National Park (KNP). However, a 1998 survey failed to detect any sign of *V. komodoensis* on Padar Island, a small mountainous island (20 km^2) within KNP, suggesting that this population was extirpated (Ciofi and deBoer 2004. Herpetol. J. 14:99–107). In 1969–1970, Auffenberg (*op. cit.*) had estimated that ca. 60 dragons inhabited this hilly and largely savannah-covered island. Anecdotal evidence suggests that this population of *V. komodoensis* had been extirpated by the early 1980s, possibly because of illegal harvesting of the Timor Deer (*Cervus timorensis)*, their preferred prey.

Recently, reports from fishermen plying local waters have suggested the renewed presence of *V. komodoensis* on Padar Island. To confirm these reports, we conducted trapping and visual surveys on Padar Island over five days in December 2004. To assess for *V. komodoensis* presence, direct and indirect methods were used. Direct methods involved the placement of two aluminium box traps (300 cm × 50 cm × 50 cm) baited with ca. 0.5 kg of goat meat. These traps were positioned in the largest forested valley on

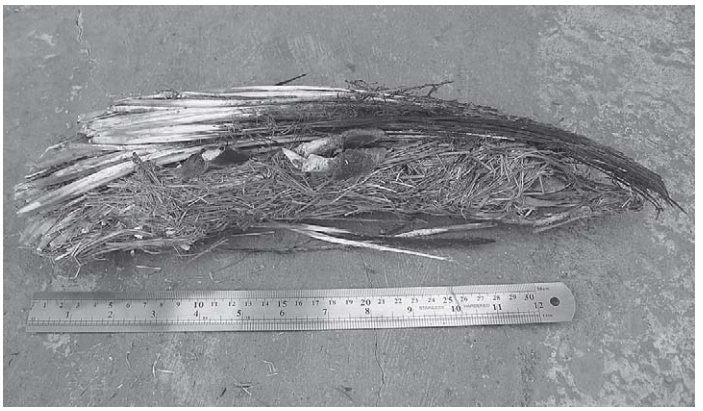

FIG. 1. Gastric pellet believed to be that of a Komodo Dragon collected from Padar Island that contains the flight feathers from a sea bird (top of pellet) and the hoof of a juvenile Timor Deer (mid center of pellet) surrounded by a matrix of grass. For scale, the ruler is 30 cm.

the south eastern corner of the island. Indirect methods involved focal searches along 30 × 150 m long transects randomly positioned across the island from which any signs of *V. komodoensis* were recorded. Transects were concurrently used for assessing the density of Timor Deer, based on fecal pellet counts. Visual sampling was also conducted between transects when walking to the start point of the next transect. The purpose of indirect sampling was to identify potential signs specific to Komodo Dragons, including: 1) gastric pellets or large boluses of indigestible food matter (keratin and often bone-based material) encased in grass, that *V. komodoensis* regurgitate after ingestion of prey; 2) foot or tail tracks or burrows; and 3) feces.

Despite laying out two baited traps, no *V. komodoensis* were captured or directly sighted on Padar over the trapping period. However, fresh tracks with the characteristic accompanying tail drag and a body pit that was likely to have been made on the day of sampling were recorded on a beach (8.656417°S, 119.600722°E, datum: WGS, elev. 4 m) ca. 1.3 km WSW from our trap locations. In addition, we found several feces (8.655175ºS, 119.5814722ºE; and 8.6554917ºS; 119.5814361ºE) that contained the remains of sea turtle eggs (either *Eretmochelys imbricata* or *Chelonia mydas*), and *C. timorensis*, prey items consistent with *V. komodoensis*. However, the sign most suggestive of *V. komodoensis* presence was a 40 cm × 10 cm gastric pellet (Fig. 1). This pellet contained the remains of deer bones and fur, and the remains of a large raptor (probably a White-bellied Sea Eagle, *Haliaeetus leucogaster*).

Our results suggest that either *V. komodoensis* engaged in inter-island movement or that the species was not completely extirpated on Padar Island. Based on the low density of tracks and scats, only one dragon may now occupy Padar Island. If inter-island movement was the source of this animal, the closest occupied islands would be Rinca (1.95 km) and Komodo Island (4.71 km). Anecdotal reports indicate that *V. komodoensis* has some capacity to swim and thus potentially move among islands. However, the frequency of such events in both ecological (TJ, unpubl. data) and evolutionary time (Ciofi and Bruford 1999. Mol. Ecol. 8:17–30) seems infrequent, suggesting that fidelity of individuals to their respective islands is high. Even within islands, dragons are very rarely recorded to move among valleys (TJ, unpubl. data).

VARANUS KOMODOENSIS (Komodo Dragon). **PARASITES.** Ticks that parasitize varanid lizards are primarily from the genera *Amblyomma* and *Aponomma* (King and Green 1999. Goannas: The Biology of Varanid Lizards. Univ. New South Wales Press, Sydney. 116 pp.). Ticks as ectoparasites consume host blood, cause disease, and can function as important vectors for microparasites, which can negatively influence fitness (Main and Bull 2000. Oecologia 122:574–581). *Varanus komodoensis*, a large monitor lizard from southeastern Indonesia, has been documented to carry three species of tick, including *Amblyomma helvolum*, a generalist, and two host-specific species: *A. robinsoni* and *Aponomma komodoense* (Auffenberg 1981. The Behavioral Ecology of the Komodo Monitor. University Press of Florida, Gainesville, Florida. 406 pp.). However, little is known about either the general ecology or fitness implications of this host-parasite relationship. One aspect of this relationship that remains unknown is the possibility that ticks have evolved strategies to parasitize hatchling dragons upon emergence from their nests. From a parasite's perspective, the host environment of juvenile animals provide the least resistance with respect to immunological (i.e., lack of acquired immunity) or physical (e.g., skin thickness) barriers. Hence, here we report on the ability of ticks to parasitize hatchling Komodo Dragons recently emerged from three nests on Komodo Island.

In January of each observation year (2003–2006), a sample of known active nests of *V. komodoensis* were caged to enable capture of hatchlings as part of routine annual monitoring of the ecology and life-history of this species in Komodo National Park (Jessop et al. 2004. Biol. Conserv. 117:463–470). Prior to emergence in March/April (late wet season), nest cages were monitored twice daily (morning and afternoon coinciding with emergence of hatchlings from the ground) to enable measurement and marking of individual hatchlings prior to release. In 2004, we also examined for the presence of ectoparasites of hatchlings on Komodo Island, one of four extant populations within Komodo National Park.

From the three nests monitored on Komodo Island in 2004 (referred to as A, B, and C), 47 Komodo hatchlings were captured in March (estimated within 4 h post-emergence). These hatchlings averaged 95.5 ± 2.2 g in mass and 18.8 ± 0.1 cm SVL. Hatchlings from two of the three nests were found to be carrying nymphal ticks of one species, *Aponomma komodoense*. Two of 12 hatchlings (16.6%) from Nest A had ticks; one had 1 tick, the other had 3 (Table 1). Clutch B had 16 individuals, 9 (56.3%) of which carried ticks. The number of ticks ranged from 1 to 20, with an average number of ticks per hatchling of 7.4 ± 2.5. Hatchlings (N = 18) from Nest C lacked ticks.

Our results indicate that alongside larger Komodo Dragons, hatchlings can act as tick hosts. By parasitizing hatchlings on emergence, ticks could greatly increase their capacity to find new and,

potentially of greater importance, immunologically naïve hosts (i.e., no acquired resistance). Female dragons, which act as hosts for ticks, spend considerable periods of time around the nest both prior to and after oviposition and thus could enable ticks to deposit eggs (that remain quiescent) around the nest site until hatchlings emerge. Seasonal cues, including the conspicuous transition from an extended dry season through to the short summer wet season coinciding with the monsoon represent an important cue for many organisms breeding in the wet-dry tropics of Australasia (Madsen et al. 2006. Aust. J. Ecol. 31:30–37). This seasonal cue could provide necessary environmental information enabling nymphal ticks to synchronise their own hatching and questing activity with the emergence of hatchling dragons. At present, we do not know whether ticks impart specific fitness consequences to their hatchling hosts.

SQUAMATA – SNAKES

AGKISTRODON CONTORTRIX (Copperhead). **DIET.** *Agkistrodon contortrix* is known to take a variety of prey items, including the snakes *Carphophis amoenus*, *C. vermis*, *Coluber constrictor*, *Crotalus lepidus*, *Diadophis punctatus*, *Rhinocheilus lecontei*, *Storeria dekayi*, and *Tantilla coronata* (McCrystal and Green 1986. Herpetol. Rev. 17:61; Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. Society for the Study of Amphibians and Reptiles, Oxford, Ohio. 614 pp.; Palmer and Braswell 1995. Reptiles of North Carolina. University of North Carolina Press, Chapel Hill. 412 pp.; Fitch 1999. A Kansas Snake Community: Composition and Changes Over 50 Years. Krieger Publishing Co., Malabar, Florida. 165 pp.; and references therein). Here we report a novel prey item for *A. contortrix*.

On 23 May 2007 at 1415 h, one of us (JRL) captured a female *A. contortrix* (260 mm SVL, 44 mm tail length, 15 g) on the Camp Shelby Joint Forces Training Center, Perry County, Mississippi, USA. The snake appeared to have recently fed, as indicated by a large bolus in its stomach. Upon palpating, the *A. contortrix* regurgitated a female *Storeria occipitomaculata*, a gravid *Anolis carolinensis*, and a *Scincella lateralis* of undetermined sex. To the best of our knowledge this observation represents the first instance of a *S. occipitomaculata* having been consumed by an *A. contortrix*.

Submitted by **JAMES R. LEE** (e-mail: jlee@tnc.org), **AARON L. HOLBROOK**, and **JENNIFER W. FREY**, The Nature Conservancy, Camp Shelby Joint Forces Training Center, CSJFTC-ENV Building 6678, Camp Shelby, Mississippi 39407, USA.

CROTALUS MOLOSSUS (Blacktail Rattlesnake). **MORPHOLOGY**. Congenital absence of the rattle in rattlesnakes (Crotalidae) has been previously reported for *Crotalus cerastes*, *C. horridus*, and *C. pricei* by Klauber (1972. Rattlesnakes. Their Habits, Life Histories, and Influence on Mankind. Univ. California Press, Berkeley, California. 740 pp.), for *C. atrox* by Painter et al. (1999. Herpetol. Rev. 30:44) and Holycross (2000. Herpetol. Rev. 31:177–178), for *C. viridis* by Holycross (2000. Herpetol. Rev. 31:177), and for *C. lepidus* by Christman et al. (2004. Herpetol. Rev. 35:62). We report here this irregular condition of a missing rattle from another rattlesnake species discovered on a site in far west Texas.

On 6 July 2007, at 2326 h, an adult male *Crotalus molossus* (701 mm SVL, 64 mm tail length, 238.9 g) was found by two of us (LM and VMS) 0.6 km SE of the headquarters complex on Indio Mountains Research Station (IMRS) located ca. 40 km SW of Van Horn, Hudspeth County, Texas, USA (30.773056°N, 105.011944°W, WGS84; 1233 m elev.). IMRS is administered by The University of Texas at El Paso and includes 39,000 acres of rugged Chihuahuan Desert scrub landscape.

Close examination of the posterior end of the tail revealed a blunt tip with overlapping scales devoid of scar tissue, which indicates that the absence of the rattle was congenital and not the result of prior trauma. After processing for body measurements, the rattlesnake was pit-tagged (AVID #: 025-258-063) for permanent identification and then released at original capture site. Because of the snake's size and healthy condition and because the rattleless feature has been reported for adults of other rattlesnake species, we infer that lacking a rattle has negligible effects on survivability. On the other hand, the condition appears to be rare because of the 42 individuals of *C. molossus* captured and marked on IMRS since 1997, only the individual reported herein exhibited the rattleless condition. A digital image is deposited in the photographic collection, Laboratory for Environmental Biology, Centennial Museum, The University of Texas at El Paso (UTEP G2007.1.1).

LATICAUDA SAINTGIRONSI (Sea Krait). **PREDATION.** Field observations and laboratory experiments indicate that sea snakes quickly and efficiently kill their prey (fishes) by injecting potent venom (Ineich and Laboute 2002. Sea Snakes of New Caledonia. IRD et Muséum national d'Histoire naturelle Editions, Collection Faune et flore tropicales, Paris. 302 pp.). Rapid death is probably essential to foraging success in sea snakes. If death were delayed (as is the case in most species of terrestrial venomous snakes) the fish might escape and be difficult to locate in the marine environment. Here, we present the first record of any species of sea snake regurgitating a living prey item (Moray Eel, *Gymnothorax undulatus*).

In the course of conducting mark-recapture studies of large populations of *Laticauda saintgironsi* and *Laticauda laticaudata* on Signal Islet, New Caledonia (22.29°S, 166.29°E), we captured an adult male (695 mm SVL) *L. saintgironsi* on 8 December 2005 at 1740 h while it was returning from the sea. Immediately after capture, it regurgitated a *G. undulatus*. Spontaneous regurgitation is uncommon in Sea Kraits. We have captured over 3300 Sea Kraits with prey items in their stomachs and have observed less than 10

spontaneous regurgitations. Upon regurgitation, the eel dropped into shallow (5 cm) water and was not easy to catch. We rapidly placed the eel in a container filled with seawater (which we replaced every 15 min.). Initially, the eel moved slowly but was still able to swim. Multiple bite marks visible on the body and the eel's behavior suggest it had been envenomated. The eel became increasingly lethargic over time. After 78 min. it lay on its back, but righted itself after tactile stimulation with a finger. After 95 min., gill (respiratory) movements became almost undetectable. It died 110 min after the regurgitation, very likely due to the effect of the venom. Overall, the eel survived ca. two hours after being bitten, swallowed, and then regurgitated. The eel was deposited in a collection of Sea Krait prey (# 630) at the Centre d'Etudes Biologiques de Chizé (CEBC-CNRS UPR 1934). Our observations indicate that although the venom of *L. saintgironsi* certainly causes a paralysis (perhaps transitory or partial) it does not necessarily kill prey instantaneously. Our observation also indicates that *L. saintgironsi* sometimes forages very near their home islands.

We thank the Direction des Ressources Naturelles de la Province Sud, New Caledonia for issuing the necessary permits.

Submitted by **MARGOT DE CRIGNIS**, **FRANCOIS BRISCHOUX**, **XAVIER BONNET**, and **SOPHIE LORIOUX**, CEBC-CNRS UPR 1934, Centre d'Etudes Biologiques de Chizé, F-79360 Villiers en Bois, France.

MICRURUS CORALLINUS (Painted Coral Snake). **DIET.** The diet of *Micrurus corallinus* includes amphisbaenians, snakes, lizards, and also caecilians (Marques and Sazima 1997. Herptol. Nat. Hist. 5:88–91; Roze 1996. Coral Snakes of the Americas: Biology, Identification and Venoms. Krieger Publ. Co., Malabar, Florida. 328 pp.). The natural predators of *Luetkenotyphlus brasiliensis* (São Paulo Caecilian) are largely unknown (Taylor 1968. The Caecilians of the World. Kansas Univ. Press, Lawrence. 848 pp.). Here, we report a previously unpublished predator-prey relationship.

The record is based on museum specimens from the herpetological collection of the Zoological Museum Hamburg (ZMH). A *L. brasiliensis* (249 mm total length) was removed from the stomach of a *M. corallinus* (ZMH R08751; 899 mm total length) collected by Wilhelm Ehrhardt in March 1910 at "Rio Humboldt-Gebiet (Flussgebiet des Itapocú), Brasilien" (in the vicinity of the Rio Humboldt River basin of the Itapocú, Corupá, Santa Catarina, Brazil). Orientation of the prey in the gut indicates that the snake ingested the caecilian tail-first. The caudal end of the caecilian is partially digested and the last 39 vertebrae are exposed. The anterior part of the caecilian up to the 89th primary annulus is completely undamaged, which is about two-thirds of the animal compared to the 125–131 primary annuli reported for *L. brasiliensis* (Nussbaum 1986. J. Herpetol. 30:441–444).

PANTHEROPHIS VULPINA VULPINA (Western Fox Snake). **MORTALITY.** Sources of mortality in *Pantherophis vulpina vulpina* are rarely reported. Ernst and Ernst (2003. Snakes of the United States and Canada. Smithsonian Books, Washington D.C.) indicate that predatory birds take adult *P. v. vulpina*, and suggest that carnivorous mammals, automobiles, and habitat destruction might also be significant sources of mortality.

Snake mortality due to prescribed fire has been reported in other regions of North America (e.g., Durbian 2006. Am. Midl. Nat. 155:329–334; Erwin and Stasiak 1979. Am. Midl. Nat. 101:247–249; Smith et al. 2001. Southwest. Nat. 46:54–61), but has not been reported from the upper Midwest. On 16 April 2007 a prescribed fire was ignited on a 10-acre prairie preserve on the McKenzie Environmental Center near Poynette (Columbia County, Wisconsin, USA). Sunny skies, an air temperature of 17°C, and 20% humidity characterize weather conditions on the day of the burn. A post-burn survey of the property revealed a dead *P. v. vulpina* (ca. 90–105 cm TL), which had not escaped the fire. The *P. v. vulpina* was located in a corner of the burn unit where head fire, flanking fire, and backing fire converged. Flame lengths averaged ca. 3 m, giving off an estimated 980 BTUs/foot/second. Vogt (1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee. 205 pp.) suggests that *P. v. vulpina* typically emerge from winter dormancy during the last two weeks of April. If the individual caught in the fire had emerged from dormancy immediately prior to the prescribed fire, it may have been too sluggish to avoid the fire. Because prescribed fire is an effective management tool for short grass habitats, we recommend conducting burns prior to April 1 to avoid causing direct mortality to reptiles emerging from dormancy.

Snakes have been listed as a major predator of *Meleagris gallapavo* (Wild Turkey) eggs and poults (Reagan and Morgan 1980. Proc. Natl. Wild Turkey Symp. 4:136–144), and numerous bird species are reported to actively attack snakes in response to a perceived threat (e.g., Gottfried 1979. Condor 81:251–257). However, defensive attacks upon potential nest raiders are rarely reported (Hewitt [ed.]. 1967. The Wild Turkey and its Management. The Wildlife Society, Washington, D.C. 589 pp.), and those few reports involve attacks against predatory birds or mammals (Johnson 1961. Auk 78:646; Spear et al. 2003. Canad. Field Nat. 117:645–647). The potential effect of these mortality sources on snake populations, particularly in regards to *M. gallapavo* (i.e., predation of snakes and actively attacking snakes to deter a potential nest-predator) is unknown as accounts are mostly anecdotal and difficult to substantiate (but see Beasom and Pattee 1975. Wilson Bull. 87:281–282).

On 16 May 2007 at 1215 h in Polk County (Wisconsin, USA) we (MMC, KAM, and DW) observed an adult hen *M. gallapavo* repeatedly striking the head of an adult *P. v. vulpina* (ca. 1 m TL, 323 g). The bird struck the animal with both its beak and feet for approximately 20 min. MMC and KAM left for approximately 45 min to retrieve a camera and returned to find the hen still striking the snake. The hen was disturbed by their approach and flew off,

carrying the snake for a distance before dropping it. An examination revealed that, prior to the hen's attack, the snake was not underweight and bore no obvious deformities. The snake appeared to be alive throughout the majority of the attack, and attempted to defend itself against the hen before succumbing to its injuries. Although no poults or eggs were noticed, the fact that the turkey did not attempt to consume the snake, suggests that the hen's behavior was defensive rather than predatory.

Although *M. gallapavo* historically occurred in Wisconsin, they had been nearly or completely extirpated from the state by the late 1800s (Kubisiak et al. 2001. Wild Turkey Ecology and Management in Wisconsin. Wisconsin Dept. Nat. Res. PUB-SS-955 2001). Since the 1950s, significant effort has been made to re-establish populations of this species in several upper Midwestern states, including Wisconsin, with great success (Kubisiak et al. 2001, *op. cit.*). Whether turkey populations are a significant source of mortality for syntopic snake populations remains unclear.

Submitted by **MICHELLE CARLISLE**, Wisconsin Department of Natural Resources, 941 Mallard Lane #104, Balsam Lake, Wisconsin 54810, USA; **RALPH SHEFFER**, Wisconsin Department of Natural Resources, N3344 Stebbins Road, Poynette, Wisconsin 53955, USA; **KEVIN A. MORGAN**, Wisconsin Department of Natural Resources, 127 S. 4th Street, Barron, Wisconsin 54812, USA; **DOUG WAHLSTROM**, 1118 River Road, Dresser, Wisconsin 54009, USA; and **JOSHUA M. KAPFER**, Natural Resources Consulting, Inc., 119 Main Street, PO Box 128, Cottage Grove, Wisconsin 53527, USA (e-mail: jnjkapfer@hotmail.com).

PORTHIDIUM HESPERE (Western Hognose Viper). **ENDOPARASITES.** *Porthidium hespere* is limited in distribution to western Mexico where it is known only from a few specimens (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere, Vol. 1. Comstock Publ. Assoc., Ithaca, New York. 475 pp.). There are no reports of endoparasites from *P. hespere*. The purpose of this report is to establish the initial helminth list for *P. hespere*. One road-kill female *P. hespere* (total length = 30 cm) was found on Hwy 200, 2.7 km N of the turn off to El Faro de Bucerias, (18.379272°N, 103.515758°W) Michoacán, Mexico on 10 August 2005. It was deposited in the Museo de Zoologia, Facultad de Ciencias, Universidad Nacional Aútonoma de Mexico, Mexico as MZFC 19742. Three nematodes were recovered from the carcass. These were placed in a drop of glycerol on a glass slide. A cover glass was placed on top and the preparation was examined under a compound microscope. The nematodes were identified as one adult male, one adult female, and a juvenile of *Ophidascaris arndti.* These were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as USNPC (100204).

Sphren (1929. Zool. Anz. 83:280–282) described *O. arndti* from specimens recovered from a *Lachesis lanceolatus* (currently *Bothrops lanceolatus*), a Brazilian snake in the Berlin Aquarium. Sprent (1988. Sys. Parasit. 11:165–213) divided the genus into five groups of species, Group 5 (arndti group) containing two species found in South American crotalines and colubrids, *O. arndti* and *O. sicki*, respectively. Hosts for *O. arndti* also include *Bothrops atrox* (Panama), and *B. cotiara* and *Crotalus durissus* (Brazil) (Sprent, *op. cit.*). Preliminary observations suggest that *O. arndti* is transmitted to crotalines by feeding on infected rodents (Sprent, *op. cit.*). *Porthidium hespere* represents a new host record for *O. arndti*. Mexico is a new locality record.

We thank Christopher I. Grünwald for collection of the *P. hespere*.

PSAMMOPHIS BISERIATUS (Link-marked Sand Snake). **DIET**. As part of a larger study of psammophiine diets, we dissected and measured specimens of the East African species *Psammophis biseriatus* (N = 25). The sex ratio of the sample was 48% female and 52% male. None of the 20 adults examined contained prey. However, three juvenile females from Kenya had prey remains in their stomachs. CAS 131093 (516 mm SVL, 311 mm TL, 35.1 g) from Kakuma (3.70°S, 34.85°E; map datum WGS84), CAS 134502 (533 mm SVL, tail broken, 42.2 g) from near Mandera (3.93°S, 41.85°E), and CAS 165565 (474 mm SVL, 263 mm TL, 24.9 g) from near Kibwezi (2.70°S, 38.62°E) contained a *Trachylepis striata* (Striped Skink), *Trachylepis brevicollis* (Short-necked Skink), and *Hemidactylus mabouia* (Tropical House Gecko), respectively. None of the prey items extracted was intact enough for accurate measuring and weighing and all were ingested head first.

Psammophis biseriatus is a diurnal, predominately arboreal snake described as an ambush forager (Spawls et al. 2002. A Field Guide to the Reptiles of East Africa. Academic Press, San Diego. 543 pp.). Its known distribution is in eastern Africa, from western Somalia, Eritrea, and eastern Ethiopia south through Kenya to Tanzania, where its distribution becomes discontinuous (Brandstätter 1996. Die Sandrennattern. Westarp-Wissenschaften, Magdeburg, 142 pp.; Spawls et al. 2002, *op. cit.*). This species has been reported to take mostly lizard prey; however, few specific dietary records exist. Previous prey records for *P. biseriatus* are *Latastia longicaudata revoili*, *Heliobolus spekii*, *Trachylepis quinquetaentia*, *T. planifrons*, and *Chamaeleo dilepis roperi* (Loveridge 1940. Bull. Mus. Comp. Zool. 87:1–61; Spawls et al. 2002, *op. cit.*). These new prey records emphasize that scincids are important food sources for *P. biseriatus*, as they are for African *Psammophis* in general (Akani et al. 2003. J. Herpetol. 37:208–211; Shine et al. 2006. Copeia 2006:650–664), and also provide the first evidence of gekkonid prey for the species.

Submitted by **AMANDA M. COTTONE** (e-mail: amanda.cottone@villanova.edu) and **AARON M. BAUER** (e-mail: aaron.bauer@villanova.edu), Department of Biology, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085, USA.

PSAMMOPHIS CRUCIFER (Cross-marked Grass Snake). **OPHIOPHAGY**. As part of a larger study of psammophine diets, we dissected specimens of the temperate southern African species *Psammophis crucifer.* The stomach of an adult female (TM 69360, 425 mm SVL, 125 mm TL, 19.0 g) from Malolotja Nature Reserve, Swaziland (26.07°S, 31.12°E; map datum WGS84) contained a largely intact *Duberria lutrix* (Slug Eater) (186 mm SVL, 17 mm TL, 5.2 g [relative prey mass 27.2%]) that had been ingested head first. A portion of an unidentified lizard tail was found posterior to the *Duberria*. In addition, the hind gut of an adult male *P. crucifer* (PEM 974, 392 mm SVL, 168 mm TL, 20.2 g) from Port Elizabeth, Eastern Cape, South Africa (33.92°S, 25.57°E) contained the highly digested remains of a small snake that had been ingested head first. The color pattern of the remaining intact scales suggested that the prey was a *Psammophis* species, but the remains were too fragmentary to make a positive identification.

Psammophis crucifer is a habitat generalist that can be found in lowland and montane forest, moist savanna, grassland, and fynbos of southern Africa from the southwestern Cape, to the escarpment of Mpumalanga (Branch 1998. A Field Guide to Snakes and Other Reptiles of Southern Africa. Struik Publishing, Capetown, South Africa. 368 pp.). In Swaziland it co-occurs with *Duberria lutrix* in the highveld and western middleveld (Boycott 1992. A Herpetofaunal Survey of Swaziland. M.Sc. thesis, University of Natal, Durban, South Africa. v + [7] +175 pp., 43 figs.; Boycott and Culverwell 1992. J. Herpetol. Assoc. Afr. 40:38–41). It has been reported to feed chiefly on lizards, especially geckos, and frogs (Broadley 1983. FitzSimon's Snakes of Southern Africa, 3rd ed. Jonathan Ball and Ad. Donker Publishers, Parklands, South Africa. 387 pp.). The diet of most *Psammophis* species comprises predominantly lizards, frogs, or small mammals (Shine et al. 2006. Copeia 2006:650–664.) but ophiophagy has been reported in *P. phillipsi* (Haagner 1990. J. Herpetol. Assoc. Afr. 37:47; Luiselli et al. 2004. Amphibia-Reptilia 25:415–423), and the closely related *P. mossambicus* (Bruton and Haacke 1980. *In* Bruton and Cooper [eds.], Studies on the Ecology of Maputaland, pp. 251–287. Rhodes University, Grahamstown, South Africa; Broadley et al. 2003. Snakes of Zambia. An Atlas and Field Guide. Edition Chimaira, Frankfurt, Germany. 280 pp.; Shine et al., *op. cit.*), both mainly tropical in their distribution and considerably larger in size than *P. crucifer*. This record represents the first record of ophiophagy in *P. crucifer*, or any temperate southern African psammophiine.

Submitted by **AMANDA M. COTTONE** (e-mail: amanda.cottone@villanova.edu) and **AARON M. BAUER** (e-mail: aaron.bauer@villanova.edu), Department of Biology, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085, USA.

PTYAS MUCOSA (Oriental Rat Snake). **FORAGING BEHAVIOR.** *Bufo bankorensis* (Bankor Toad) is the most abundant anuran species in Da-Jiou-Shi Experimental Forest (Mao, unpubl.) and appears in the diet of *Ptyas mucosa* in Taiwan (Lin et al. 1996. NOW 3:19–21 [in Chinese]).

On 20 June 2006 at 1105 h a *P. mucosa* (ca. 1800 mm TL) was observed subduing a *B. bankorensis* on the northwestern side of a bridge over Orchid Stream (24.45722ºN, 121.67888ºE, 286 m elev.). When we approached the snake it released the toad and escaped. The toad had inflated its body and was covered in blood. Although still alive, the toad appeared to be paralyzed. Forty minutes later, when we returned to the site, we found the same snake with the same toad in its jaws. Our presence disturbed the snake and it again immediately released the toad and escaped into the nearby forest. At 1300 h we returned to the site again, and found the snake once again had the toad in its jaws. This time the snake carried the toad to the southeastern side of the stream, where it then released the toad and fled. At 1400 h when we checked for the last time, we found that the snake had returned and had almost completely ingested the toad.

Prey retrieval behavior is common in predatory birds, especially some raptors (Collopy 1977. Condor 79:63–68). In ophidians, some crotaline species will retrieve their prey after it has been envenomated (Diller 1990. J. Herpetol. 24:95–97). But in our review of the literature, we found no reports describing colubrid snakes retrieving prey they had previously abandoned. The persistence of the snake is especially interesting considering that the predation process was thrice interrupted by potential predators.

RHABDOPHIS SWINHONIS (Taiwanese Keel-back)**. DIET**. *Rhabdophis swinhonis* is a diurnal, small to medium sized snake, endemic to Taiwan. Because of its cryptic behavior, little is known of its ecology, behavior, or diet (Lue et al. 1989. Taiwan Snakes. Taiwan Provincial Dept. of Education, Taiwan, Republic of China, 94 pp. [in Chinese]). On 22 April 2006 at 1422 h in Huban District (Yunlin County) we found a *R. swinhonis* (ca. 600 mm TL) ingesting a large earthworm by the side of a trail (23.72194ºN, 120.62444ºE; 191 m elev.). To the best of our knowledge, this is the first reported prey for *R. swinhonis*.

Submitted by **JEAN-JAY MAO**, Department of Natural Resources, National Ilan University. No. 1, Sec. 1, Shen-Lung Rd., Ilan, Taiwan 260 (e-mail: jjmao@niu.edu.tw); **GERRUT NORVAL**, Applied Behavioural Ecology and Ecosystem Research Unit, Department of Nature Conservation, UNISA, Private Bag X6, Florida, 1710, Republic of South Africa; and **HSU-LIANG TSENG** and **I-SHUO TSENG**, Minshiang Environmental & Ecological Research CO., Ltd.

RHINOBOTHRYUM BOVALLII (NCN). **REPRODUCTION.** *Rhinobothryum bovallii* is a large, slender colubrid restricted to Atlantic lowlands from southern Honduras to western Venezuela and to the Pacific lowlands from central western Panama to western Ecuador (4–550 m elev.) (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). There are no published accounts of reproduction in either of the two species of *Rhinobothryum*.

Here we report on two clutches of eggs laid at the Fort Worth Zoo, Fort Worth, Texas. All of the parental snakes were captured prior to September 2000 from Guayacán de Siquirres, Limon Province, Costa Rica. Three eggs were laid by a female (1320 mm SVL, 282.0 g) on 10 February 2006. The eggs were set up in a 1.5:1 ratio of vermiculite to water at a constant 29.4ºC. Two infertile eggs were discarded on 15 and 23 February 2006. The single fertile egg (52 mm long, 18.1 mm wide, 11.7 g) was opened on 25 April 2006 revealing a seemingly fully developed dead snake (260 mm SVL, 80 mm tail, 11.4 g; University of Texas at Arlington Amphibian and Reptile Diversity Research Center, UTA R 54423) with kinked vertebrae.

A second clutch of 2 eggs (53.4 and 52.1 mm long, 17 and 17.4 mm wide, and 9.5 and 9.8 g respectively) was laid by another female (1142 mm SVL, 182.0 g) on 1 June 2006. Because high incubation temperatures often result in kinked vertebrae, this clutch was incubated on a shelf in a cooler section of the herpetarium in a substrate of 2:1 vermiculite to water by weight. Temperatures varied from a daytime high of ca. 26.6ºC to a nighttime low of ca. 21.1ºC. The morning of 26 September 2006 one egg was manually slit revealing a fully developed live neonate (307 mm SVL, 78 mm tail, 9.8 g). The second neonate (330 mm SVL, 89 mm tail, 10.0 g) hatched without assistance later the same day. All neonates had the same pattern and coloration as the adults, and both surviving neonates fed on juvenile *Anolis carolinensis* after their first ecdysis.

Submitted by **STEPHEN HAMMACK** and **ANDREW BRINKER**, Department of Herpetology, Fort Worth Zoo, 1989 Colonial Parkway, Fort Worth, Texas 76110, USA (e-mail: herp@fortworthzoo.org).

STORERIA OCCIPITOMACULATA OCCIPITOMACULATA (Northern Red-bellied Snake). **MAXIMUM SIZE**. On 2 June 2007, a gravid female *Storeria o. occipitomaculata* measuring 344 mm SVL and 422 mm TL, and weighing 18 g, was found beneath a flat rock on a wooded slope along the east side of US Hwy 62 (41.8148234°N, 79.2723545°W, WGS 84), Warren County, Pennsylvania, USA. This individual exceeds the maximum length record of 406 mm TL reported by Wright and Wright (1957. Handbook of Snakes of the United States and Canada. Comstock Publishing Associates, Ithaca, New York.). On 21 July 2007, this specimen produced a litter of 12 young, three of which were unable to escape from their egg membranes and perished. The litter size is well below the maximum of 21 reported for Pennsylvania *S. o. occipitomaculata* by Hulse et al. (2001. Amphibians and Reptiles of Pennsylvania and the Northeast. Cornell University Press, Ithaca, New York. 419 pp.). Size of the neonates (mean SVL = 71.0, SD = 7.8, range 52–76; mean TL = 91.0, SD = 9.0, range 69–97; N = 12) was slightly below the mean of 73.8 mm for SVL and 96.7 mm for TL reported by Hulse et al. (2001, *op. cit.*). The litter weighed 4 g; postpartum weight of the female was 14 g. The relative clutch mass (RCM) was 0.28, which is lower than the reported mean of 0.60 for this species (Ernst and Ernst. 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 668 pp.).

Specimens deposited in Tom Ridge Environmental Center Natural History Collections at Presque Isle State Park (TREC R-031, TREC R-032). Material that was not mounted has been deposited in the Sternberg Museum of Natural History, Fort Hays University, Hays, Kansas. We thank J. T. Collins and J. Beane for encouragement and assistance.

Submitted by **BRIAN S. GRAY,** 1217 Clifton Drive, Erie, Pennsylvania 16505, USA (e-mail: brachystoma@hotmail.com); and **MARK LETHABY,** 535 East 29th Street, Erie, Pennsylvania 16504, USA (e-mail: mlethaby@verizon.net).

THAMNOPHIS BRACHYSTOMA (Short-headed Gartersnake). **PREDATION**. *Thamnophis brachystoma* has a very limited distribution that includes the Allegheny drainage of the Allegheny High Plateau from extreme southwestern New York to northwestern Pennsylvania (Asplund 1963. Herpetologica 19:128–132) and is listed as a species of conservation concern in Pennsylvania. Herein we describe predation on *T. brachystoma* by small mammals, including *Blarina brevicauda* (Northern Short-tailed Shrew) and/or *Microtus pennsylvanicus* (Meadow Vole).

During spring and summer 2005 we recorded vertebrates encountered under an array of 24 sheets of plywood and ca. 34 m^2 of corrugated asphalt (Ondura brand) boards. The coverboard array was located in DuBois, Clearfield County, Pennsylvania (USA) in a seasonally flooded wet meadow dominated by grass and forbs. The coverboard array was checked a total of 38 times during the period 13 April – 19 September at least once a week. On 4 July, 9 September, and 19 September boards were checked twice each day. The three most common vertebrates under the boards in order of occurrence were *T. brachystoma* (N = 183), *M. pennsylvanicus* (N = 81), and *Thamnophis sirtalis* (Eastern Garter Snake; N = 22). *B. brevicauda* (N = 9), *Condylura cristata* (Star-nosed Mole; N = 9), and *Diadophis punctatus* (Ring-necked Snake; N = 1) were also observed. Numerous grass nests were found under the plywood boards and five litters of young *M. pennsylvanicus* were recorded.

On five occasions we found dead *T. brachystoma* under coverboards. In two cases the snakes' head and neck were missing, with the most anterior part of the spine exposed and soft tissue removed, as if stripped off by a predator. These snakes had 38 cm and 33 cm of body and tail length remaining, indicating they were adults. A third dead snake was a 15 cm long juvenile with head and body intact but signs of mutilation on the head and body. The largest dead snake (38 cm remaining) was found with the anterior spine dangling down into a soil crack. Soil cracks were common under the plywood coverboards and snakes and small mammals escaped into them when the boards were lifted. On 23 Sept 2004 (prior to the start of our formal surveys) we observed a dead *T. brachystoma* under the same board as a large food cache of seven earthworms (dead, dying, partially paralyzed or eaten) and snail shells. Although the head was missing, 21 cm of the snake's body remained. A female *B. brevicauda* was captured under the same coverboard in close proximity to the cache two days prior. On 28 Sept 2004 the posterior portion (6 cm) of another freshly killed *T. brachystoma* was found under the same coverboard. A *B. brevicauda* was also under the coverboard in an extensive grass nest (ca. 30 cm in diameter). On four occasions *T. brachystoma* and *M. pennsylvanicus* were found under a plywood board at the same time. The snakes and voles were found from 25

cm to 46 cm apart, and lifting the board caused one or both of the animals to flee for cover.

Small mammals, birds of prey (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, London. 668 pp.), and other reptiles (Rossi and Rossi 2003. Snakes of the United States and Canada: Natural History and Care in Captivity. Krieger Publishing Co., Malabar, Florida. 520 pp.) are reported as potential predators of *T. brachystoma*. However, we were unable to find other reports of predation by specific small mammals on this species. The close association of the garter snakes and *M. pennsylvanicus* and *B. brevicauda* under the coverboards and repeated observations of mutilated *T. brachystoma* under the boards suggests that one or both of these mammals is killing these snakes.

Submitted by **JOSEPH W. HUMMER** and **KEELY TOLLEY ROEN**, Pennsylvania State University, DuBois Campus, 1 College Place, DuBois, Pennsylvania, USA (e-mail: kat175@psu.edu).

THAMNOPHIS EQUES (Mexican Gartersnake). **ENDOPARASITISM.** *Thamnophis eques* ranges from the vicinity of the Pico de Orizaba northwest through Sonora and Chihuahua, Mexico to Arizona and New Mexico in the United States (Conant 2003. Amer. Mus. Novit. 3406:1–64). On 15 October 2006 we found an adult male *T. eques* (620 mm SVL, 820 mm TL; Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México, CNAR 12229) dead on the bank of Laguna de Yuriria, Guanajuato, Mexico (20.2777°N, 101.1111°W). The snake's mid-body was swollen and upon dissection we found two fourth-stage larvae of *Eustrongylides* sp. in the mesentery and some lesions in the surrounding tissues. Both nematodes were alive, red in color, and measured 97 mm and 124 mm in length (Colección Nacional de Helmintos, Instituto de Biología, Universidad Nacional Autónoma de México, CNHE 5599).

Larval forms of *Eustrongylides* sp. have been reported from *Nerodia sipedon* in Accomack County, Virginia, USA (Bursey 1986. J. Wildl. Dis. 22:527–532), from *T. eques* in Lago de Pátzcuaro, Mexico, and *T. melanogaster* in Pátzcuaro and Cuitzeo Michoacán lagoons, Mexico (Jiménez et al. 2002. J. Parasitol. 88:454–460). Death of captive *T. sirtalis*, with swellings in the body due to infection by *Eustrongylides* sp., has been reported (Lichtenfels and Lavies 1976. Lab. Anim. Sci. 26:465–467). *Eustrongylides* spp. adults have been reported from birds throughout much of the world and are associated with disease and even death in many avian species (Franson and Custer 1994. Colon. Waterbirds 17:168–172; Wiese et al. 1977. J. Wildl. Dis. 13:376–382). The life cycle of this genus of nematodes includes freshwater oligochaetes as first intermediate hosts, fish as second intermediate hosts, and piscivorous birds as definitive hosts. Amphibians and reptiles have been recorded as paratenic hosts (Cooper et al. 1978. J. Parasitol. 64:102–107; Yamaguti 1961. Systema Helminthum. Vol III. The Nematodes of Vertebrates. Interscience Publishers, Inc. New York. 669 pp.). In this context, our observation raises the possibility that infection of *T. eques* by *Eustrongylides* sp. larvae might be a cause of mortality in some wild populations.

Submitted by **ELISA CABRERA GUZMÁN,** Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Circuito exterior, Ciudad Universitaria, México D. F. C.P. 04510; e-mail: anfisbenido@yahoo.com.

TRIMORPHODON VILKINSONII (Chihuahuan Lyre Snake). **ARBOREAL BEHAVIOR**. *Trimorphodon vilkinsonii* is a secretive snake that ranges throughout the central and western regions of the Chihuahuan Desert. This species has primarily been encountered in rock piles, rock outcroppings, and talus slopes (Werler and Dixon 2000. Texas Snakes: Identification, Distribution, and Natural History. University of Texas Press). *Trimorphodon biscutatus* is known to be arboreal (Scott and McDiarmid 1984. Cat. Amer. Amph. Rep. 353.1–353.4), as is *T. lambda* (Lowe 1964. The Vertebrates of Arizona. University of Arizona Press, Tucson); however, arboreality has yet to be noted in *T. vilkinsonii*. Here we report on two separate instances of aboreality in this species.

We found a female *T. vilkinsonii* (TNHC 66487; 591 mm SVL, 115 mm TL, 37.4 g) on 5 May 2007 at 2143 h in Cottonwood Canyon of the Sierra Vieja, Presidio County, Texas (30.54739°N, 104.67831°W, 1483 m elev.). This snake was climbing one of the main trunks of a large Gray Oak (*Quercus grisea*) and was 3.35 m above the ground. The cluster of oaks was located where the canyon bottom and rocky talus slope meet. A second female *T. vilkinsoni* (TNHC 66513; 715 mm SVL, 131 mm TL, 88 g) was found on 29 June 2007 at 2230 h in Box Canyon, a drainage on the eastern side of the Sierra Vieja, Presidio County, Texas (30.55059°N, 104.65919°W, 1378 m elev.). The female was found crawling among the outer branches of a Catclaw Acacia (*Acacia gregii*) approximately 1 m above the ground and 2 m from the dry wash.

Both specimens were collected under Texas Parks and Wildlife Scientific Collecting Permit SPR-1097-912 to Travis J. LaDuc. We thank the Miller family for support and assistance.

HIBBITTS**, Texas Cooperative Wildlife Collection, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843-2258; USA.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother [ed.] 2008. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico*. SSAR Herpetol. Circ. 37:1–84, available from SSAR Publications Secretary, ssar@herplit.com; for Mexico as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish.* Herpetol. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data, including lat/long coordinates in **decimal degrees** and cite the map datum used), DATE (day-month-year), COLLECTOR,

VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state or province names—no abbreviations). If publishing specific locality information for a rare or endangered species has the potential to jeopardize that population, please consult with the Section Editor at time of record submission. If field work and/or specimen collection occurred where permits were required, please include permit number(s) and authorizing agency.

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the photographic catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*; available from the SSAR Publications Secretary) and other sources to make sure you are not duplicating a previously published record. The responsibility for checking literature for previously documented range extensions lies with authors. **Do not submit range extensions unless a thorough literature review has been completed.**

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: **Alan M. Richmond** (USA & Canadian records only); **Jerry D. Johnson** (Mexico and Central America, including the Caribbean Basin); **Indraneil Das** (all Old World records); or **Gustavo J. Scrocchi** (South American records). Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Electronic submission of manuscripts is required** (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments)**.** Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Schmitz, A., and T. Ziegler. 2003. Geographic distribution. *Sphenomorphus rufocaudatus*. Herpetol. Rev. 34:385.

CAUDATA – SALAMANDERS

AMBYSTOMA MACULATUM (Spotted Salamander). USA: ARKANSAS: Desha Co.: 4.8 km SE Dumas off US 65 (Sec. 11, T10S, R4W). 12 April 2006. Nick Covington. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30819). New county record filling a distributional gap between previous records in Lincoln (Robison 2006. Herpetol. Rev. 37:481) and Arkansas counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

Submitted by **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@saumag.edu); and **CHRIS T. McALLISTER**, Department of Physical and Life Sciences, Chadron State College, Chadron, Nebraska 69337, USA (e-mail: cmcallister@csc.edu).

AMBYSTOMA MACULATUM **(**Spotted Salamander). USA: TENNESSEE: Weakley Co: Greenfield (36.2031667°N, 88.8884333°W). 14 November 2007. Joshua M. Hall. Verified by A. Floyd Scott. Austin Peay State University's David H. Snyder Museum of Zoology (APSU 18822 [color slide]). One adult specimen found beneath damp log. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Austin Peay State Univ. Misc. Publ. 12:1–94; Redmond and Scott 1996. Atlas of Amphibians in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. http//www.apsu.edu/amatlas/).

Submitted by **JOSHUA M. HALL**, Union University, 4105 Caldwell Drive, Milan, Tennessee 38358, USA.

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). USA: ARKANSAS: Praire Co.: Hazen (34.7776444°N, 91.5866444°W). 18 October 2007. Jeffery Hunter Sebern. Verified by Stanley E. Trauth. Arkansas State University Museum of Zoology Herpetological Collection (ASUMZ 30821). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MICHAEL V. PLUMMER**, Department of Biology, Box 12251, Harding University, Searcy, Arkansas 72149, USA (e-mail: plummer@harding.edu), **SARAH G. JOHNSON**, and **JOHN R. JOHNSON,** 2401 Audley Bolton, Searcy, Arkansas 72143 USA (e-mail: scientificker@hotmail.com).

ANEIDES AENEUS **(**Green Salamander). USA: INDIANA: Perry Co.: Hoosier National Forest: 38.3 m W of Crawford County Line (38.12133°N, 86.46278°W). 14 November 2007. Angela Garcia. Verified by Chris Phillips, Illinois Natural History Survey (INHS 2007e). New county record (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science. vii–404 pp.) This observation is outside of Indiana's proposed range, suggesting an undiscovered westward projection of a population along the bluffs of the Ohio River. The salamander was captured by hand alongside a small crevice within a rock outcrop. *Aneides aeneus* is a state endangered species, previously known to occur in only two isolated populations in Crawford County.

Submitted by, **ANGELA GARCIA**, **NATHAN ENGBRECHT**, **JAMIE FALLER**, and**, ZACK WALKER**, Wildlife Diversity Section, Indiana Department of Natural Resources Division of Fish and Wildlife, 553 E. Miller Drive, Bloomington, Indiana 47401, USA (e-mail: zwalker@dnr.IN.gov).

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: ARKANSAS: Perry Co.: 5.6 km NE Hollis, T3N, R19W, Sec18. 19 October 2007. Tobin Fulmer and Destiny Fulmer. Verified by Renn Tumlison. Henderson State University Museum of Zoology (HSUMZ 1412, 1413). Two adults were found under a log in a wooded area. New county record extends known range 24 km N of closest record (Saugey and Trauth 1991. Proc. Arkansas. Acad. of Sci. 45:88–91). A closer specimen, HSU 1086, 16.3 km S, is cataloged in the HSU collection.

Submitted by **TOBIN FULMER,** Arkansas Natural Heritage Commission, 1500 Tower Building, 323 Center Street, Little Rock, Arkansas 72201, USA; and **DESTINY FULMER**, 2305 Laverne Street, Bryant, Arkansas 72022 USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: INDIANA: Tippecanoe Co.: Brookston 7.5 minute USGS quad map; SW 1/4 of Sec. 21, T24N, R3W. 04 May 2005. Kyle W. Arvin. Verified by Christopher Phillips. Illinois Natural History Survey (INHS photo voucher 2007c). First record for county (Minton 2001. Amphibians and Reptiles of Indiana, rev. 2nd ed.,

Indiana Academy of Science, Indianapolis, Indiana).

First specimen found in upland woods under a log. On 06 May, 07 May and 08 May, 2005, additional specimens were found under logs in upland woods habitat by Kyle Arvin, Delano Arvin, and Rick Howard. On 14 May 2005, LAC found a female attending well-developed eggs in a clump of sedge and mosses. The nesting location was an open, spring-fed wetland dominated by clumps of sedges (*Carex* spp.), skunk cabbage (*Symplocarpus foetidus*), and marsh marigold (*Caltha palustris*). The wetland used for nesting was adjacent to the upland woods where the other salamanders were found.

Submitted by **LEE A. CASEBERE**, Indiana Department of Natural Resources, Division of Nature Preserves, 402 W. Washington Street, Rm. W-267, Indianapolis, Indiana 46204, USA (e-mail: Lcasebere@dnr.in.gov); and **KYLE W. ARVIN**, New York State Seed Testing Laboratory, New York State Agricultural Experiment Station, Cornell University, Sturtevant Hall, 630 West North Street, Geneva, New York 14456, USA (e-mail: kwa3@nysaes.cornell.edu).

NOTOPTHALMUS VIRIDESCENS (Eastern Newt). USA: ARKANSAS: Lonoke Co.: 2.2 km E Ward (T5N, R9W, S25). 3 April 2005. Donald F. McKenzie. Verified by Stanley E. Trauth. Arkansas State University Museum of Zoology Herpetological Collection (ASUMZ 30822). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.).

Submitted by **MICHAEL V. PLUMMER**, Department of Biology, Box 12251, Harding University, Searcy, Arkansas 72149, USA (e-mail: plummer@harding.edu); and **DONALD F. McKENZIE,** Wildlife Management Institute, 2396 Cocklebur Road, Ward, Arkansas 72176, USA (e-mail: wmidm@ipa.net).

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: ARKANSAS: Lincoln Co.: county road 21 at Ten Mile Creek S of Cornerville (Sec. 27, T10S, R8W). 16 March 2006. Henry W. Robison. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30820). New county record partially filling a distributional gap between Cleveland and Desha counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

Submitted by **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@saumag.edu); and **CHRIS T. McALLISTER**, Department of Physical and Life Sciences, Chadron State College, Chadron, Nebraska 69337, USA (e-mail: cmcallister@csc.edu).

ANURA – FROGS

ACRIS CREPITANS (Northern Cricket Frog). USA: TENNESSEE: Haywood Co.: Hatchie National Wildlife Refuge, Hillville 35.48599°N, 89.19597°W. 20 May 2004. Jonathan W. Stanley. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18222, audio voucher). First county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **JONATHAN W. STANLEY,** Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467, USA; and **BRIAN P. BUTTERFIELD**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340, USA (e-mail: bbutterfield@fhu.edu).

ACRIS CREPITANS (Northern Cricket Frog). USA: TENNESSEE: Tipton Co.: Bear Creek at the junction of Bluff, Coon Valley, Herring, and Pryor roads in the Drummonds 7.5 Minute Quad (35.44682°N, 89.96216°W; NAD83). 17 July 2007. Joshua R. Ennen and Brian R. Kreiser. Verified by A. Floyd Scott. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 18806). One adult captured upstream from bridge in an isolated pool in the flood plain. First record for Tipton County (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 16 pp. Hard copy and Internet (http//www.apsu.edu/amatlas/) versions, the latter of which includes links to information on Tennessee amphibians that has appeared since 1996; accessed 1 November 2007).

The voucher specimen was collected by authors under authority of Tennessee Wildlife Resources Scientific Collecting Permit 1662 and deposited in Austin Peay State University's Museum of Zoology, APSU 18806.

Submitted by **JOSHUA R. ENNEN** (e-mail: Joshua.Ennen@usm.edu) and **BRIAN R. KREISER,** Department of Biological Science, University of Southern Mississippi, Hattiesburg, Mississippi 39406, USA (e-mail: brian.kreiser@usm.edu).

ANAXYRUS AMERICANUS (American Toad). USA: TENNESSEE: Knox Co.: Hardin Valley Area (35.94468°N, 084.20568°W). 06 August 2007. Ted M. Faust. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18815, color photo). One individual was found on the front porch of a house shortly after sunset at 2105 h. Air temperature 25°C. Two more individuals were found in a nearby flower garden within an hour and a half of the first individual. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter [http://www.apsu.edu/amatlas/ accessed 07 August 2007] including links to data on amphibians in Tennessee that have appeared since 1996).

Submitted by **TED M. FAUST**, 11828 Couch Mill Road, Knoxville, Tennessee 37932, USA; e-mail: tmfaust21@gmail.com.

ANAXYRUS FOWLERI (Fowler's Toad). USA: TENNESSEE: Morgan Co.: 5.4 km SW of Lancing (36.0941194°N, 84.703147°W). 11 May 2007. Ted M. Faust. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18814, color photo). One individual was found at the base of a bluff at 0940 h. A second individual was found under an overhanging bluff at 1045 h. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter [http://www.apsu.edu/amatlas/ accessed 07 August 2007] including links

to data on amphibians in Tennessee that have appeared since 1996).

Submitted by **TED M. FAUST**, 11828 Couch Mill Road, Knoxville, Tennessee 37932, USA; e-mail: tmfaust21@gmail.com.

ELEUTHERODACTYLUS CYSTIGNATHOIDES (Rio Grand Chirping Frog). USA: LOUISIANA: LAFAYETTE PARISH: Zoo of Acadiana grounds (30.1171333°N, 91.93995°W). 19 April 2007. James W. Beck and Robert C. Dobbs. Color photograph verified by David Cannatella. TNHC 66880. This individual was singing from exotic grass ca. 1 m above the ground within a natural area among zoo buildings, at ca. 2100 h under humid conditions. This represents the first documented record for Lafayette Parish (Dundee and Rossman 1989. Amphibians and Reptiles of Louisiana, Louisiana State Univ. Press, Baton Rouge. 300 pp.), and only the second documented state record (Hardy 2004. Southwest. Nat. 49:263–268). This species is expanding its range to the north and east, presumably as a result of human activity, and is now established throughout much of southeastern Texas, north to Smith and Nacogdoches counties (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M Univ. Press, College Station. 421 pp.; Hibbitts and Saenz 2007. Herpetol. Rev. 38:350), and in Caddo Parish in northwestern Louisiana (Hardy 2004, *op. cit.*).

Submitted by **JAMES W. BECK**, 100 Aurelien Loop #101, Broussard, Louisiana 70518, USA (e-mail: agkistrodon@worldnet.att.net); and **ROBERT C. DOBBS**, Department of Biology, Queen's University, Kingston, Ontario K7L 3N6, Canada (e-mail: 6rcd1@queensu.ca).

GASTROPHRYNE CAROLINENSIS (Eastern Narrow-mouthed Toad). USA: TENNESSEE: GIBSON CO.: Milan (35.970314647°N, 88.714316025°W). 29 April 2007. Joshua M. Hall. Verified by A. Floyd Scott. Austin Peay State University's David H. Snyder Museum of Zoology (APSU 18801 [color slide]). One adult specimen found underneath damp log. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Austin Peay State Univ. Misc. Publ. 12:1–94; Redmond and Scott 1996. Atlas of Amphibians in Tennessee The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. http://www.apsu.edu/amatlas/).

Submitted by **JOSHUA M. HALL**, Union University, 4105 Caldwell Drive, Milan, Tennessee 38358, USA.

GASTROPHRYNE CAROLINENSIS (Eastern Narrow-mouthed Toad). USA: TENNESSEE: HAYWOOD CO.: Hatchie National Wildlife Refuge, Hillville (35.48599°N, 89.19597°W) 20 May 2004. Jonathan W. Stanley. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18221, audio voucher). First county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **JONATHAN W. STANLEY,** Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467, USA; and **BRIAN P. BUTTERFIELD**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340, USA (e-mail: bbutterfield@fhu.edu).

HYLA AVIVOCA (Bird-voiced Treefrog). USA: TENNESSEE: FAYETTE CO.: Wolf River Wildlife Management Area, Mineral Slough (35.0292998°N, 89.2734998°W). 05 May 2007. J. Ream and E. Johansen. Verified by A. Floyd Scott. Austin Peay State University's David H. Snyder Museum of Zoology (APSU 18816). Voucher specimen collected by hand at 2200 h along the westernmost shore of a water tupelo/cypress slough adjacent to the Wolf River; many other individuals calling in vicinity. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter [http://www.apsu.edu/amatlas/ accessed 20 November 2007] including links to data on amphibians in Tennessee that have appeared since 1996).

Submitted by **JOSHUA TAYLOR REAM**, Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA; e-mail: jream14@apsu.edu.

HYLA CINEREA (Green Treefrog). USA: TENNESSEE: TIPTON CO.: Bear Creek at the junction of Bluff, Coon Valley, Herring, and Pryor roads in the Drummonds 7.5-minute quad (35.44682°N, 89.96216°W; NAD83). 17 July 2007. Joshua R. Ennen and Brian R. Kreiser. Verified by A. Floyd Scott. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 18806). One adult captured upstream from bridge in an isolated pool in the flood plain. First record for Tipton County (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 19 pp. Hard copy and Internet (http//www.apsu.edu/amatlas/) versions, the latter of which includes links to information on Tennessee amphibians that has appeared since 1996; accessed 1 November 2007).

The voucher specimen was collected by authors under authority of Tennessee Wildlife Resources Scientific Collecting Permit 1662 and deposited in Austin Peay State University's Museum of Zoology, APSU 18805.

Submitted by **JOSHUA R. ENNEN** (e-mail: Joshua.Ennen@usm.edu) and **BRIAN R. KREISER,** Department of Biological Science, University of Southern Mississippi, Hattiesburg, Mississippi 39406, USA (e-mail: brian.kreiser@usm.edu).

HYLA GRATIOSA (Barking Treefrog). USA: GEORGIA: ATHENS-CLARKE CO.: Whitehall Forest, off of Phoenix Rd. (33.8906°N, 83.3578333°W; WGS 84). 21 August 2007. Collected by Andrew Richard Ferreira. Verified by John Jensen. UGAMNH (GMNH 50083). New county record (Williamson and Moulis 1994. Distribution of Amphibians and Reptiles in Georgia. Savannah Sci. Mus. Spec. Publ. No. 3, Savannah, Georgia. 712 pp.; Mitchell. 2005. *In* M. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 455–456. University of California Press, Berkeley, California). An adult *H. gratiosa* was found in a plastic cattle tank which held ca. 10 cm of water. On 18 and 29 September 2007, three metamorphic individuals (Gosner Stage 42; Gosner 1960. Herpetologica 16:183–190) were dip-netted from the edge of a pond within Whitehall Forest, located 0.5 km from above specimen location (33.8886139°N, 83.3628°W; WGS 84). The adult and metamorphic individuals suggest a breeding population in Whitehall Forest, Athens-Clarke County, Georgia.

HYLA VERSICOLOR (Gray Treefrog). CANADA: ONTARIO: TIMISKAMING DISTRICT: South Lorrain Twp., southern terminus of Hwy 567 at Ontario Power Generation's Lower Notch Generating Station (47.1386°N, 79.4542°W; NAD27). 21 August 2007. Richard Burns. Royal Ontario Museum (ROM) 43033, digital photograph. Verified by Ross D. MacCulloch. One individual perched on a steel platform at the top of an 18 m metal tower at approximately 1300–1500 h (sunny, air temperature 20°C). First record for Timiskaming District, extending its documented range ca. 80 km ENE of the Sheppard Twp. location, ca. 98 km NNW of the location E of North Bay, and ca. 119 km NW of the location W of Deux-Rivières. Reduces the hiatus in NE Ontario 165 km to the NW between this record and an undocumented observation near Parting Lake (47.9703°N, 81.2825°W; NAD27), and another undocumented observation 225 km to the NNW at Nahma Bog, (48.9214°N, 80.8839°W; NAD27).

The documented northern range limit in northeastern Ontario is represented by specimens from the following three localities (west to east): Sudbury Dist., Sheppard Twp., near Sturgeon River (46.9315°N, 80.4555°W; NAD27), uncatalogued larvae identified by F. R. Cook, but material housed at Canadian Museum of Nature (formerly National Museum of Canada, NMC) – 1994; Nipissing Dist., 17 km E of North Bay on Hwy 17 (46.2671°N, 79.2481°W; NAD27), NMC 7067 – May 1963); and, Nipissing Dist., 21 km W of Deux-Rivières on Hwy 17 (46.2850°N, 78.5141°W; NAD27), NMC 28778 – September 1986).

PSEUDEMYS CONCINNA (River Cooter). USA: ALABAMA: Autauga Co.: Alabama River, 0.5 km downstream of Steele's Landing at southern end of Autauga Co. Rd. 1 (32.4318111°N, 86.8381472°W). 23 May 2007. Peter V. Lindeman. Verified by James Godwin. Three adults photographed from close range at 30× with a Kowa spotting scope with built-in digital camera. Florida Museum of Natural History Herpetology Dept. photographic archive (UF 152447). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.). Dallas Co.: Alabama River, 1 km upstream of Edmund Pettus Bridge in Selma (32.4062°N, 87.0149722°W). 23 May 2007. Peter V. Lindeman. Verified by James Godwin. Adult male photographed from close range at 30× with a Kowa spotting scope with built-in digital camera. Florida Museum of Natural History Herpetology Dept. photographic archive (UF 152448). New county record (Mount 1975, *op. cit.*)

Submitted by **PETER V. LINDEMAN**, Department of Biology and Health Services, 150 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA; e-mail plindeman@edinboro.edu.

STERNOTHERUS ODORATUS (Eastern Musk Turtle). USA: WISCONSIN: Manitowoc Co.: Pigeon Lake (43.9877778°N, 87.8763889°W). 25 July 2007. Stephen Surendonk. Photographs verified by Robert Hay (Wisconsin Department of Natural Resources-Bureau of Endangered Resources) and Gary Casper. Illinois Natural History Survey catalogue number: INHS 2007d. New county record. Extends range of species in Wisconsin (Casper 1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, 87 pp.). One individual captured in a fyke net.

Submitted by **STEPHEN SURENDONK**, Wisconsin Department of Natural Resources, 2220 E. County Highway V, Mishicot, Wisconsin 54228, USA; and **JOSHUA M. KAPFER**, Natural Resources Consulting, Inc., 118 Main St, PO Box 128, Cottage Grove, Wisconsin 53527, USA.

TERRAPENE ORNATA LUTEOLA (Desert Box Turtle). USA: ARIZONA: Pinal Co.: Gila River floodplain, ca 4.2 km (airline) W and 0.2 km (airline) N Gila Co. line at Hwy 177 (W of Hayden), 33.0058°N, 110.8402°W; NAD27; 571 m elev. 23 July 2004. N. Olsker, H. Messing. UAZ 56315-PSV. Within 60 m of San Pedro River, Old PZ Ranch site, S of Dudleyville, (32.8743°N, 110.7224°W; NAD27), 625 m elev. 29 September 2004. R. Llewellyn. UAZ 56302-PSV. Alongside road, ca 0.6 km (airline) SSE Cook's Lake, 32.8546°N, 110.7160°W; NAD27; 657 m elev. 10 August 2003. D. Hall. UAZ 56325-PSV. E side San Pedro River, 9.7 km (by River Rd) SSE Copper Creek Rd (32.6642°N, 110.5930°W; NAD2), 738 m elev. 21 July 2005. R. Bezy, K. Bezy, K. Bolles. UAZ 56301-PSV. ARIZONA: Cochise Co.: San Pedro River Valley, ca 3.3 mi (by Cascabel Rd) SE Cascabel (32.2617°N, 110.3348°W; NAD27), 976 m elev. 22 July 2002. D. Hall. UAZ 56330-PSV. All verified by George Bradley.

These include the first records for Pinal County and extend the range 120 km N from the Whetstone Mts., Cochise County (Turner et al. 2003. Southwest. Nat. 48:347–355) and 40 km NW from Aravaipa Creek and the Bonita grasslands, Graham Co. (Nickerson and Mays 1970. Trans. Kansas Acad. Sci. 72:492–505). The scattering of these records along a 90 km stretch of the lower San Pedro River north to the Gila River floodplain suggests that the populations found in this riparian corridor within the Sonoran Desert are native rather than introduced (released captives).

SQUAMATA –LIZARDS

ACANTHOSAURA LEPIDOGASTER (Scale-bellied Spiny Lizard). THAILAND: NAKHON RATCHASIMA PROVINCE: Pak Chong District: Khao Yai National Park, nr. Lamtakong Stream (14.4322222°N, 101.4094444°E) 670 m elev. 09 October 2007.

M. Cota. Thailand Natural History Museum (THNHM-image/071002). Verified by T. Chan-ard. Previously known from northern Thailand and an isolated location in northern peninsular Thailand. Southeastern most record in Thailand, extending known range 230 km S from its nearest previous locality in Phu Khieo National Park, Khon San District, Chaiyaphum Province (Nabhitabhata et al. 2000. Checklist of Amphibians and Reptiles in Thailand. OEPP, Bangkok. 152 pp.; Nabhitabhata and Chan-ard 2005. Thailand Red Data: Mammals, Reptiles and Amphibians. OEPP, Bangkok. 234 pp.). This report represents the sole record in Thailand east of the Chao Phraya River basin and the flood plain region.

Submitted by **MICHAEL COTA**, Thailand Natural History Museum, National Science Museum, Technopolis, Khlong 5, Khlong Luang, Pathum Thani 12120 Thailand; e-mail: Herpetologe@gmail.com.

ELGARIA COERULEA PRINCIPIS (Northwestern Alligator Lizard). USA: IDAHO: VALLEY CO.: A single individual was observed ca. 4.6 km NE of Edwardsburg along the Big Creek Trail about 200–400 m downstream of the trailhead in the Frank Church River of No Return Wilderness, Payette National Forest (45.1538°N, 115.2935°W; NAD 83). 24 July 2006. Javan Bauder, Ashley Lange, and Brad Tucker. Color voucher photo deposited at the Idaho Museum of Natural History (IMNH 1923). Verified by Charles R. Peterson. Individual was crawling across dirt trail towards a talus slope at ca. 1700 h with sunny skies and 40–50% cloud cover. Had lost all but ca. 3 cm of its tail, the last ca. 1 cm of which appeared to be regrowth. New county record for this species, which extends the range ca. 105 km S of nearest unpublished observation (Idaho Co., Idaho; Bill Bosworth, Idaho Conservation Data Center, Idaho Department of Fish and Game, pers. comm.). Nearest published observations are ca. 195 and 225 km NW in Latah Co., Idaho (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press, Moscow, Idaho; Cossel 1997. *Elgaria coerulea*. Digital Atlas of Idaho, http://imnh.isu.edu/digitalatlas/ bio/reptile /main/ repfram.htm, respectively).

Submitted by **JAVAN BAUDER**, Department of Fish and Wildlife Resources, University of Idaho, Moscow, Idaho 83844, USA. Current addres: Department of Biological Sciences, Idaho State University, Pocatello, Idaho 83209, USA; e-mail: baudjava@isu.edu.

HELIOBOLUS NITIDUS NITIDUS (Günther's Desert Lacertid). NIGER: Koure village (13.3433333°N, 02.57515°E; 408 m elev.). L. Chirio and I. Ineich. MNHN 2007.0038–51. Verified by Patrick David. First country record. Extends known range of subspecies 200 km N and into a former country gap, and previously known from Ivory Coast (Rödel et al. 1997. Salamandra 33[4]:225–240 [as *H. n. nitida*]), unreported from Ghana, Togo (Tornier 1901. Arch. Naturgesch., Beiheft Festschrift für Eduard von Martens, pp. 63–88), Benin (Loveridge 1952. Bull. IFAN, Dakar, sér. A, 14:229–242), and Nigeria (Dunger 1967. The Nigerian Field 32[3]:117–132 [as *Eremias nitida*]). A second subspecies, *H. n. garambensis* is known from Cameroon (Monard 1951. Mém. l'IFAN, sér. Sci. Nat. 1:123–170), Central African Republic (Joger 1990. *In* Peters and Hutterer [eds.], Vertebrates in the Tropics. Museum Alexander Koenig, Bonn; Chirio and Ineich 2006. African J. Herpetol. 55[1]:23–59), and Democratic Republic of Congo (formerly Zaire) (Schmidt 1919. Bull. Amer. Mus. Nat. Hist. 39:385–624 [as *Eremias nitida*]). Papenfuss (1969. Wasmann J. Biol. 27[2]:249–325) considered the species as inhabiting west African savannas from Guinea to Cameroon, but distribution clearly extends more to the east.

Submitted by **IVAN INEICH** and **LAURENT CHIRIO**, Muséum national d'Histoire naturelle, Département de Systématique et Evolution, USM 602 (Reptiles – Taxonomie et Collections) CP 30, 25 rue Cuvier, 75231 Paris Cedex 05, France; e-mail: ineich@mnhn.fr.

HEMIDACTYLUS TURCICUS TURCICUS (Mediterranean Gecko). USA: TEXAS: WILLIAMSON CO.: Georgetown, Sun City, N of Berry Creek bridge on Del Webb Blvd. 10 May 2007, DOR. TNHC 66523 (JLC 7136). Georgetown, 4304 Miramar. 01 August 2007. TNHC 66524 (JLC 7141*)*. BELL CO. Residence wall on farm road 2484, 3.5 mi. S. of Texas 195. 31 July 2007. TNHC 66525 (JLC 7145*)*. Verified by Travis LaDuc. First county records; fills in records for central Texas. (Dixon 2000. Amphibians and Reptiles of Texas. 2nd Edition. Texas A&M Univ. Press, College Station, 421 pp.).

Submitted by **JAMES L. CHRISTIANSEN**, Texas Natural History Collections, Texas Natural Science Center, The University of Texas at Austin, Austin, Texas 78705, USA; and **RICHARD WOOLHEATER,** 136 Fox Home Lane, Georgetown, Texas 78633, USA.

HEMITHECONYX CAUDICINCTUS (Fat-tailed Gecko). MAURITANIA: GUIDIMAKA REGION: 2 km NW Mbalou village (15.0333333°N, 12.083333°W). 15 November 2003. Jean-François Trape and Georges Diatta. Institut de Recherche pour le Développement at Dakar (IRD TR-166). Verified by Ivan Ineich. First record for Mauritania. A large adult male measuring 205 mm (122 + 83). Found inside a termitarium, ca. 2 m high during a study of borreliosis, when examining the content of a hole by introducing a flexible tube and sucking out contents with a portable petrol-powered aspirator (Vial et al. 2006. Lancet 368:37–43). Most records are from Sudan or Guinea savannah regions, and only two reach the 15th parallel: at Nioro du Sahel (15.233333°N, 09.5833333°W) in Mali, and Yonoféré (15.2666667°N, 14.466666°W) in Senegal (Grandison 1956. Bull. IFAN. 18[A]:224–245; Cisse and Karns 1978. Bull. IFAN. 40:144–211).

Submitted by **JEAN-FRANÇOIS TRAPE** and **GEORGES DIATTA**, Institut de Recherche pour le Développement (IRD, UR 77), B.P. 1386, Dakar, Sénégal; e-mail: trape@ird.sn.

PHYSIGNATHUS COCINCINUS (Chinese Water Dragon). THAILAND: NONG KHAI PROVINCE: SANGKHOM DISTRICT: Sangkhom Forest Reserve/Research Center for Medicinal Plants and Spices, along Nam Prai Stream (18.08°N, 102.2105556°E), 223 m elev.). 17 October 2007. M. Cota. Thailand Natural History Museum (THNHM 12868). Verified by T. Chan-ard. Previously known from eastern Thailand and an isolated locality in Sakon Nakhon Province. Northwestern most record, extending known range 220 km WNW from nearest record in Sakon Nakhon Province and N > 350 km from eastern Thailand at its closest point in Nakhon Ratchasima Province (Nabhitabhata et al. Checklist of

Amphibians and Reptiles in Thailand. OEPP, Bangkok. 152 pp.; Nabhitabhata and Chan-ard 2005. Thailand Red Data: Mammals, Reptiles and Amphibians. OEPP, Bangkok. 234 pp.). This report places the species in the region that transitions from the Khorat Plateau to the mountainous region that forms the topography of northern Thailand. The majority of the Khorat Plateau does not possess suitable habitat and is used primarily for agriculture, but it is possible that there are other isolated populations in areas retaining forest cover and permanent streams, canals, or rivers.

Submitted by **MICHAEL COTA**, Thailand Natural History Museum, National Science Museum, Technopolis, Khlong 5, Khlong Luang, Pathum Thani 12120 Thailand; e-mail: Herpetologe@gmail.com.

SCINCELLA LATERALIS (Little Brown Skink). USA: ARKANSAS: Chicot Co.: 3.2 km N jct. St. Hwy. 8 in Eudora (Sec. 14, T18S, R2W). 18 May 2004. D. J. Monks. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30818). New county record. This skink has now been documented for all 75 counties of the state (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.).

Submitted by **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@saumag.edu); and **CHRIS T. McALLISTER**, Department of Physical and Life Sciences, Chadron State College, Chadron, Nebraska 69337, USA (e-mail: cmcallister@csc.edu).

SPHAERODACTYLUS ELEGANS ELEGANS (Ashy Gecko). USA: FLORIDA: Broward Co.: Pembroke Pines: 1031 NW 93rd Ave (26.0168833°N, 80.2695694°W; WGS84; elev. <1 m). 27 October 2007. Collected by Lisa A. Charlton. Verified by F. Wayne King, Florida Museum of Natural History, University of Florida. One neonate captured in Jackson sticky trap set to sample insects in an alee tree (*Blighia sapida*). UF 152418. New county record. Originally turned in to Division of Plant Industry (DPI), Florida Department of Agriculture and Consumer Services, Gainesville, Florida, on 31 October 2007; Entomology Log No. 8204. This nonindigenous gecko was first reported from Key West, Monroe County, Florida, more than 85 years ago (Stejneger 1922. Copeia [108]:56). Since that time the species has slowly expanded its range through other islands in the Florida Keys, and onto mainland Florida in Miami, Miami-Dade County (Carr 1940. Univ. Florida Publ. Biol. Sci. Ser. 3[1]:1–118; Krysko and Daniels 2005. Caribb. J. Sci. 41:28–36.). On 11 September 1937, a single *Sphaerodactylus e. elegans* was collected in Port Everglades, Broward County, Florida (UF 183) and on 26 January 1963, another collected from inside a house in Miami, Miami-Dade County, Florida (UF 84234). This latest specimen is the third known mainland record in the continental U.S.

Submitted by **LOUIS A. SOMMA**, Department of Zoology, PO Box 118525, 223 Bartram Hall, University of Florida, Gainesville, Florida 32611-8525, USA (e-mail: las@zoo.ufl.edu); and **KENNETH L. KRYSKO**, Division of Herpetology, Florida Museum of Natural History, Dickinson Hall, University of Florida, Gainesville, Florida 32611, USA (e-mail: kenneyk@flmnh.ufl.edu).

TROPIDOPHORUS ASSAMENSIS (Assamese Water Skink). INDIA: ASSAM: Barail Hill Range, Adakuchi Basti Nullah (24.993°N, 92.7424°E), 163 m elev. 1215 and 1300 h on 29 March 2007. One example (SVL 41.23 mm; BNHM 1783) and another (SVL 68.65 mm; in private collection, AD/BR 05) collected from under bryophyte-covered rocks of evergreen forest streambed. Third specimen photographed from Lakhicherra Nullah, Barail Wildlife Sanctuary (24.9473667°N, 92.7781833°E), 40 m elev., 1022 h on 2 April 2007, under rocks of slow-flowing stream. Verified by Indraneil Das. Previously known from Nengpui Wildlife Sanctuary of Mizoram (Pawar and Birand 2001. A Survey of Amphibians, Reptiles and Birds in Northeast India, CERC Technical Report #6, Centre for Ecological Research and Conservation, Mysore. 118 pp.). First record from Assam state and ca. 300 km N of previous locality.

Submitted by **ABHIJIT DAS**, Division of Herpetology, Aaranyak, Samanwoy Path, Survey, Beltola, Guwahati 28, Assam, India; e-mail: abhijit@aaranyak.org.

SQUAMATA – SNAKES

AGKISTRODON BILINEATUS (Cantil). MÉXICO: SONORA: Municipality of Rosario Tesopaco, 13.2 m N of Tesopaco on Hwy 12. (ca. 27.81°N, 109.35°W). 13 August 1991. Randall D. Babb, Peter J. Mayne, Adam B. Schwalbe, and Amy Haddock. Verified by Charles H. Lowe and Cecil R. Schwalbe. UAZ 56577-PSV (specimen given to the Centro De Ecológico de Sonora). Northernmost record for this species in México and extends the known range ca. 120 km NW from the closest known locality near Alamos, Sonora (Schwalbe and Lowe 2002. *In* Robichaux and Yetman [eds.], The Tropical Deciduous Forest of Alamos, pp. 172–199. Univ. Arizona Press, Tucson, Arizona). The adult male was DOR in an area of tropical dry forest.

Submitted by **RANDALL D. BABB**, Arizona Game and Fish Department, Region VI Office, 7200 E. University, Mesa, Arizona, 85207, USA (e-mail: rbabb@azgfd.gov); and **ERIC A. DUGAN**, Department of Earth and Biological Sciences, Loma Linda University, Loma Linda, California 91330-9303, USA (e-mail: edugan1@hotmail.com).

CARPHOPHIS VERMIS (Western Wormsnake). USA: ARKANSAS: Lafayette Co.: Stamps (Sec. 21, T16S, R23W). 05 October 1989. J. Davis. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30824). New county record partially filling distributional gap between Columbia and Hempstead counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). Most records of this snake are in central and northern Arkansas (Trauth et al. 2004, *op. cit.*, fig. 493). Although extensive southern gaps remain, the species has now been reported from five counties in the extreme southern part of the state (see also Robison and McAllister 2007. Herpetol. Rev. 38:245–246).

Submitted by **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@saumag.edu); and **CHRIS T. McALLISTER**, Department of Physical and Life Sciences, Chadron State College, Chadron, Nebraska 69337, USA (e-mail: cmcallister@csc.edu).

CEMOPHORA COCCINEA (Scarletsnake). USA: FLORIDA: LAFAYETTE CO.: 0.48 km N of County Road 360 on State Road 51 (30.01245°N, 83.1937833°W), 2219 h. 4 June 2004. Michael E. Welker and Michael Arnold. Verified by Kenneth L. Krysko. Florida Museum of Natural History, Gainesville, Florida (UF 142711, 142712). New county record and range extension (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second Edition. Windward Publishing, Miami, Florida. 176 pp.). These two specimens were found DOR at the same location. Both were adult males and both have 8-8 upper labials. Further, the first black body blotch is separated from the parietal scales by one scale in both specimens. The Northern Scarletsnake (*C. c. copei*) usually has 6-6 upper labials and the first black body blotch touches the parietal scales. The Florida Scarletsnake (*C. c. coccinea*) usually has 7–7 upper labials and the first black body blotch is separated from the parietal scales by one to four scales. Thus these two specimens appear to more closely resemble the morphological characters for *C. c. coccinea*, the Florida Scarletsnake. However, *C. c. coccinea* is known to occur about 90 miles to the south at the northern extent of its range.

Submitted by **MICHAEL E. WELKER**, 3105 Eads Place, El Paso, Texas 79935, USA (e-mail: herpcon@cox.net); and **MICHAEL ARNOLD**, 1911 NW 55th Terrace, Gainesville, Florida 32605, USA (e-mail: marnold35@cox.net).

COLUBER CONSTRICTOR (North American Racer). USA: MINNESOTA: FILLMORE CO.: County Road 27, ca. 3.2 km W of River Road (east of Rushford). 5 October 2007. Stephen J. Schmitt and Philip A. Cochran. James Ford Bell Museum (JFBM 15217). Verified by Kenneth H. Kozak. DOR. First county record (Oldfield and Moriarty 1994. Amphibians & Reptiles Native to Minnesota. University of Minnesota Press, Minneapolis, Minnesota. 237 pp.).

Submitted by **STEPHEN J. SCHMITT** (e-mail: sjschm04@smumn.edu) and **PHILIP A. COCHRAN,** Biology Department, Saint Mary's University of Minnesota, 700 Terrace Heights, Winona, Minnesota 55987, USA (e-mail: pcochran@smumn.edu).

DIADOPHIS PUNCTATUS REGALIS (Regal Ring-necked Snake). USA: IDAHO: JEROME CO.: A single individual was observed ca. 10.4 km S of Jerome within the Snake River Canyon (42.6303°N, 114.5168°W; NAD83/WGS84). 31 May 2001. Javan Bauder and Jared Bauder. Color voucher photo deposited at the Idaho Museum of Natural History (IMNH 1922). Verified by Charles R. Peterson. Individual was lying in cheatgrass at the base of a large boulder ca. 1130 h with sunny skies and <10% cloud cover. Surrounding area consisted of scattered boulders intermixed with cheatgrass. First county record. Extends the published range of this species west ca. 170 km. An unpublished observation of *D. p. regalis* was made from Twin Falls County, Idaho, on the rim of the Snake River Canyon, ca. 6 km SE on 03 April 2006 (Bill Bosworth, Idaho Conservation Data Center, Idaho Department of Fish and Game, pers. comm.), suggesting that these observations may represent a previously undocumented population. Nearest published observations of *D. p. regalis* are from Bannock County, Idaho (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press, Moscow, Idaho; Cossel 1997. Digital Atlas of Idaho, http://imnh.isu.edu/digitalatlas/bio/reptile /main/ repfram.htm). *Diadophis punctatus* is also documented from Boise County, Idaho, ca. 190 km NW (Nussbaum et al. 1983, *op. cit.*) and is reported as *D. p. occidentalis* (Wright and Wright 1957. Handbook of Snakes of the United States and Canada. Comstock Publishing Associates, Ithaca, New York).

Submitted by **JAVAN BAUDER**, Department of Biological Sciences, Idaho State University, Pocatello, Idaho 83209, USA; e-mail: baudjava@isu.edu.

ECHINANTHERA CEPHALOSTRIATA (NCN). BRAZIL: BAHIA: Municipality of Jussari, Boa Vista farm. 24 August 1992. M. O. Santos. Coleção Zoológica Gregório Bondar, of the Centro de Pesquisas do Cacau, Ilhéus, Bahia (CZGB 2045); Municipality of Arataca, Alto Rocha farm (15.1533333°S, 39.3025°W, 600–700 m elev.). 10 May–25 June 2001. Collector unknown. Museu de Zoologia da Universidade Estadual de Santa Cruz, Ilhéus, Bahia (MZUESC 1213); Municipality of Barra do Choça, Recanto da Adriana farm (14.9588889°S, 40.5491667°W, 800–900 m elev.) 02 May–29 November 2004. J. O. Ruas. (MZUESC 4337). Municipality of Pau Brasil, Mira Serra farm (15.3722222°S, 39.59°W, 600–700 m elev.) 05 October 2005–01 February 2006. Collector unknown. (MZUESC 4820). Precise data of the last three specimens are unknown, dates indicate periods between visits to the farms. All verified by V. Germano. The species was known from Espirito Santo to northeastern Santa Catarina, Brazil (Di-Bernardo 1996. The Snake 27:120–126). First state records extend known range 550 km N of Santa Teresa, the previous nearest locality known.

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO,** Universidade Estadual de Santa Cruz – UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45662-000, Ilhéus, Bahia, Brazil (e-mail: lachesis@uesc.br); and **JULIANA ALVES DE JESUS,** Rua Tertuliano Guedes de Pinho, n. 60, Apt 201, Bairro Jaçanã, CEP 45608-455, Brazil (e-mail: juli_dae@hotmail.com).

LAMPROPELTIS TRIANGULUM ELAPSOIDES (Scarlet Kingsnake). USA: FLORIDA: HAMILTON CO.: 21.1 km N of U.S. 41 on County Road 135 (30.4850167°N, 82.7112667°W), 1923 h. 10 May 2004. Michael E. Welker and Michael Arnold. Verified by Kenneth L. Krysko. Florida Museum of Natural History, Gainesville, Florida (UF 142709). New county record and range extension (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second Edition. Windward Publishing, Miami, Florida. 176 pp.). This large adult male was captured alive as it began to enter the roadway. It died in captivity on 29 June 2004.

Submitted by **MICHAEL E. WELKER**, 3105 Eads Place, El Paso, Texas 79935, USA (e-mail: herpcon@cox.net); and **MICHAEL ARNOLD**, 1911 NW 55th Terrace, Gainesville, Florida 32605, USA (e-mail: marnold35@cox.net).

LYCODON JARA (Yellow-speckled Wolf Snake). INDIA: HARYANA: Kalesar National Park (30.8°N, 77.34°E), 314 m elev. 13 March 2007. A. N. Rizvi. Northern Regional Station, Zoological Survey of India, Dehra Dun, Uttarakhand. ZSI NRS R.61. Verified by Indraneil Das. First record from Haryana State. Known from Dehra Dun (Uttarkhand), Ganjam (Orissa), east to the eastern Indian states of West Bengal and Arunachal Pradesh (Whitaker

and Captain 2004. Snakes of India. The Field Guide. Draco Books, Chennai. xiv + 481 pp.), and extension of range to the west by ca. 75 km W of Dehra Dun.

Submitted by **ARCHANA BAHUGUNA** and **P. T. BHUTIA**, 218 Kaulagarh Road, Dehra Dun 248195, Uttarakhand, India; e-mail: bahugunaarch_nandini@yahoo.co.in.

MICRURUS FULVIUS (Harlequin Coralsnake). USA: FLORIDA: LAFAYETTE CO.: 5.15 km N of Dixie County line on County Road 357 (29.86575°N, 83.2381167°W), 1700 h. 2 May 2004. 0.97 km N of Dixie County line on County Road 357 (29.8337333°N, 83.237116°W), 1915 h. 29 September 2004. Michael E. Welker and Michael Arnold. Verified by Kenneth L. Krysko. Florida Museum of Natural History, Gainesville, Florida (UF 141545, 142710). New county record and range extension (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second Edition. Windward Publishing, Miami, Florida. 176 pp.). The first specimen (UF 141545) was an adult and the second specimen (UF 142710) was a small juvenile. Both were found DOR.

Submitted by **MICHAEL E. WELKER**, 3105 Eads Place, El Paso, Texas 79935, USA (e-mail: herpcon@cox.net); and **MICHAEL ARNOLD**, 1911 NW 55th Terrace, Gainesville, Florida 32605, USA (e-mail: marnold35@cox.net).

PSAMMODYNASTES PICTUS (Painted Mock Viper). INDONESIA: SULAWESI: Propinsi Sulawesi Tenggara, Kabupaten Kolaka Utara, Kecamatan Lasusua, Desa Tobaku (3.4166667°S, 120.8666667°E), 19–27 m elev. 13 August 2007. J. A. McGuire, R. A. Chong, B. J. Evans, C. W. Linkem, R. Elianur, N. P. Sumanto, and A. Rasit. JAM (Jimmy A. McGuire field series, uncataloged voucher at MZB or MVZ, 7289–91). 4 September 2007. J. A. McGuire, R. A. Chong, C. J. Hayden, N. P. Sumanto, Umilaela, and A. Rachmansyah. (JAM 8352–69, 8422). Verified by D. T. Iskandar. Easternmost record (Stuebing and Inger 1999. A Field Guide to the Snakes of Borneo. Natural History Publications [Borneo] Sdn. Bhd., Kota Kinabalu. vii + 254 pp.). The range currently includes Malaysia, Singapore, and Indonesia (Borneo, Riau Archipelago, and Sumatra), but has not been previously reported from Sulawesi (de Lang and Vogel 2006. The Snakes of Sulawesi. A Field Guide to the Land Snakes of Sulawesi with Identification Keys. Edition Chaimaira, Frankfurt am Main. 312 pp.). A total of 22 individuals were collected: 12 males (SVL 350–435 mm), six females (SVL 360–389 mm), and four juveniles (SVL 230–295 mm). All collected in vegetation alongside or overhanging a small, highly disturbed stream within cacao plantations. Due to the disturbed nature of the habitat and the abundance of specimens collected at this one site, even after thorough sampling of surrounding areas, we suspect it was introduction through human agencies on the island.

Submitted by **REBECCA A. CHONG** (e-mail: rchong@berkeley.edu), and **JIMMY A. MCGUIRE** (e-mail: mcguirej@berkeley.edu), Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA (e-mail: mcguirej@berkeley.edu).

REGINA RIGIDA RIGIDA (Glossy Crayfish Snake). USA: FLORIDA: LAFAYETTE CO.: 7.6 km E of State Road 51 on County Road 360 (29.9918833°N, 83.1198333°W), 2348 h. 13 May 2005. Michael E. Welker and Michael Arnold. Verified by Kenneth L. Krysko. Florida Museum of Natural History, Gainesville, Florida (UF 144324). New county record and range extension (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second Edition. Windward Publishing, Miami, Florida. 176 pp.). This specimen was found writhing in the road, apparently after just being hit by a motor vehicle. It died a short time later.

Submitted by **MICHAEL E. WELKER**, 3105 Eads Place, El Paso, Texas 79935, USA (e-mail: herpcon@cox.net); and **MICHAEL ARNOLD**, 1911 NW 55th Terrace, Gainesville, Florida 32605, USA (e-mail: marnold35@cox.net).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). USA: FLORIDA: LAKE CO.: Astatula, Lake Co. Landfill, 1.1 km SE of junction of State Road 19 and County Road 448 (28.7581667°N, 81.7453333°W; WGS84). 06 December 2007. Ridge Kaiser, Jennifer L. Matusick, and Julie Hanson. Florida Museum of Natural History photographic voucher (UF 152547). Verified by Kenneth L. Krysko. New county record. This exotic species has now been collected from at least 18 counties in Florida (Somma 2007. Herpetol. Rev. 38:355–356), and it has been documented from two adjacent counties, Seminole (Owen et al. 1998. Herpetol. Rev. 29:115) and Orange (Ernst and Brown 2000. Herpetol. Rev. 31:256). The specimen was found while excavating Gopher Tortoise (*Gopherus polyphemus*) burrows at a landfill.

Submitted by **LISA FAIRCHILD,** LPG Environmental and Permitting Services, Inc., 1174 Camp Avenue, Mount Dora, Florida 32757, USA (e-mail: lfairchild@lpgenvironmental.com); and **KEVIN M. ENGE**, Florida Fish and Wildlife Conservation Commission, 4005 South Main Street, Gainesville, Florida 32601, USA (e-mail: kevin.enge@myfwc.com).

SISTRURUS CATENATUS EDWARDSII (Desert Massasauga). USA: NEW MEXICO: SANTA FE CO.: 3.9 km S and 4.2 km E of Stanley (35.1128°N, 105.9337°W; NAD83/WGS84); 1925 m elev. 6 September 2007. J. N. Stuart and A. Q. Roberts. Verified by J. Tomasz Giermakowski. University of New Mexico Museum of Southwestern Biology (MSB 73380). New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xx + 431 pp.) and second record for the Estancia Basin of New Mexico (Stuart and Brown 1996. Herpetol. Rev. 27:214).

Submitted by **JAMES N. STUART** and **AARON Q. ROBERTS**, New Mexico Department of Game and Fish, Conservation Services Division, Santa Fe, New Mexico 87504-5112, USA (e-mail: james.stuart@state.nm.us).

STORIERIA OCCIPITOMACULATA (Red-bellied Snake). USA: ILLINOIS: MCDONOUGH CO.: Spring Lake (40.50309°N, 90.72056°W) On hiking trail. 28 August 2005. Collected by Benjamin R. Wodika. Verified by Michael A. Romano. Western Illinois University Herpetology collection 14161. Adult, 21.0 cm SVL. New county record. This species was believed to be present in the area, but there are few voucher specimens from surrounding counties. (INHS. Illinois Natural History Survey. http://

www.inhs.uiuc.edu/cbd/herpdist/species/st_occipit.html http. Accessed 10 Oct 2007; Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8. Champaign, Illinois. 282 pp.)

Submitted by **BENJAMIN R. WODIKA**, Department of Biological Sciences, Western Illinois University, 1 University Circle Macomb, Illinois, USA.

VIRGINIA VALERIAE VALERIAE (Eastern Smooth Earthsnake). USA: FLORIDA: WALTON CO.: 3.7 km S of State Road 20 on County Road 83A East (30.46945°N, 86.1536333°W), 0035 h. 08 April 2005. Michael E. Welker. Verified by Kenneth L. Krysko. Florida Museum of Natural History, Gainesville, Florida (UF 144325). New county record and range extension (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Second Edition. Windward Publishing, Miami, Florida. 176 pp.). This specimen, along with three Okaloosa County specimens (UF 99675, 115415, 117732), help fill a large gap in this species' range along the gulf coast in the panhandle of Florida. This specimen was found DOR after a heavy rain.

Submitted by **MICHAEL E. WELKER**, 3105 Eads Place, El Paso, Texas 79935, USA**;** e-mail: herpcon@cox.net.

The Endau-Rompin National Park is located at the southern end of Peninsular Malaysia. It encompasses 87,000 ha across the southernmost portion of the Banjaran Titi Wangsa mountain range in the states of Pahang and Johor (Fig. 1). The park is comprised of lowland mixed dipterocarp forests, flood plains, riparian environments, and hill top dipterocarp forests. The three highest peaks in the Johor section are Gunung Tiong (1014 m) near the center of the park, Gunung Bekok (953 m) in the west, and Gunung Besar (1036 m) in the northwest, all of which are flanked by many other smaller hills.

To date there have been three published herpetological surveys of the Johor section of Endau-Rompin (Daicus and Hashim 2004; Kiew 1987; Lim 1989), two amphibian surveys on the northern side in Pahang (Norhayati et al. 2004a,b), and an unpublished senior thesis on the amphibians from the Johor portion (Bhaarathyraja 2006). Collectively, these surveys listed one species of caecilian, 48 frogs, 4 turtles, 26 lizards, and 17 snakes. In addition to the herpetological surveys, there have been several other scientific surveys (zoological, botanical, and geological) conducted between 1985 and 2004 (Malayan Nature Society 1988; Shaharuddin et al. 2004).

Presented here are the results of a survey conducted in the Peta region (04°28.318'N, 101°22.635'E) on 24–31 August 2005 and in Selai (02°26.000'N, 103°15.283'E) from 30 August to 5 September 2006 (Fig. 1). Peta comprises 1600 ha of pristine lowland rainforest and Selai, which lies 26 km to the south, comprises 660 ha of similar habitat. These lowland regions are characterized by mixed dipterocarp forests and are crisscrossed by several small streams and one large river, Sungai Endau. New species records presented below are based on voucher specimens deposited in the Zoological Reference Collection (ZRC) at The Raffles Museum of Biodiversity Research, National University of Singapore, the La Sierra University Herpetological Collection (LSUHC), and a collection deposited in the Nature Education Research Center (NERC) in Peta. Voucher photographs of some species are deposited in the La Sierra University Digital Photograph Collection (LSUDPC). An up-to-date checklist of the herpetofauna of Endau-Rompin is presented in Table 1. The taxonomies of Frost et al. (2006) for the *Bufo quadriporcatus* group, Matsui et al. (2005) for *Microhyla*, Gower et al. (2002) for the Ichthyophiidae, Shaffer et al. (1997) for the higher classification of turtles, Carranza and Arnold (2006) for *Hemidactylus*, Mausfeld and Schmitz (2003) for *Eutropis*, Vogel and Van Rooijen (2007) for *Dendrelaphis*, Utiger et al. (2002) for Old World rat snakes, David and Das (2004) for *Ptyas*, David et al. (2006) for the *Trimeresurus puniceus* complex, and Malhotra and Thorpe (2004) for the Viperidae are followed. The following species are newly recorded for the park.

Anura

Ansonia endauensis Grismer, 2006. (Fig. 2). Peta; Sungai Kawal, 31 August 2005, ZRC 1.11555–58.

Ingerophrynus gollum Grismer, 2007. Peta; Sungai Kawal. 28 August 2005. ZRC 1.11569–71.

Microhyla butleri Boulenger, 1900. Peta; Visitor center, 25 August 2005, LSUHC 7619.

Micryletta inornata (Boulenger, 1890). (Fig. 3). Peta, Visitor center, 26 August 2005, LSUHC 7626.

Limnonectes plicatellus (Stoliczka, 1873). (Fig. 4). Selai; Sungai Ketiau Padi. 1 September 2006, LSUHC 8175.

Rana laterimaculata Barbour and Noble, 1916. Peta; Visitor center. 25 August, LSUHC 7634.

Rana miopus Boulenger, 1918. Johor, Endau-Rompin: NERC 50720. No data.

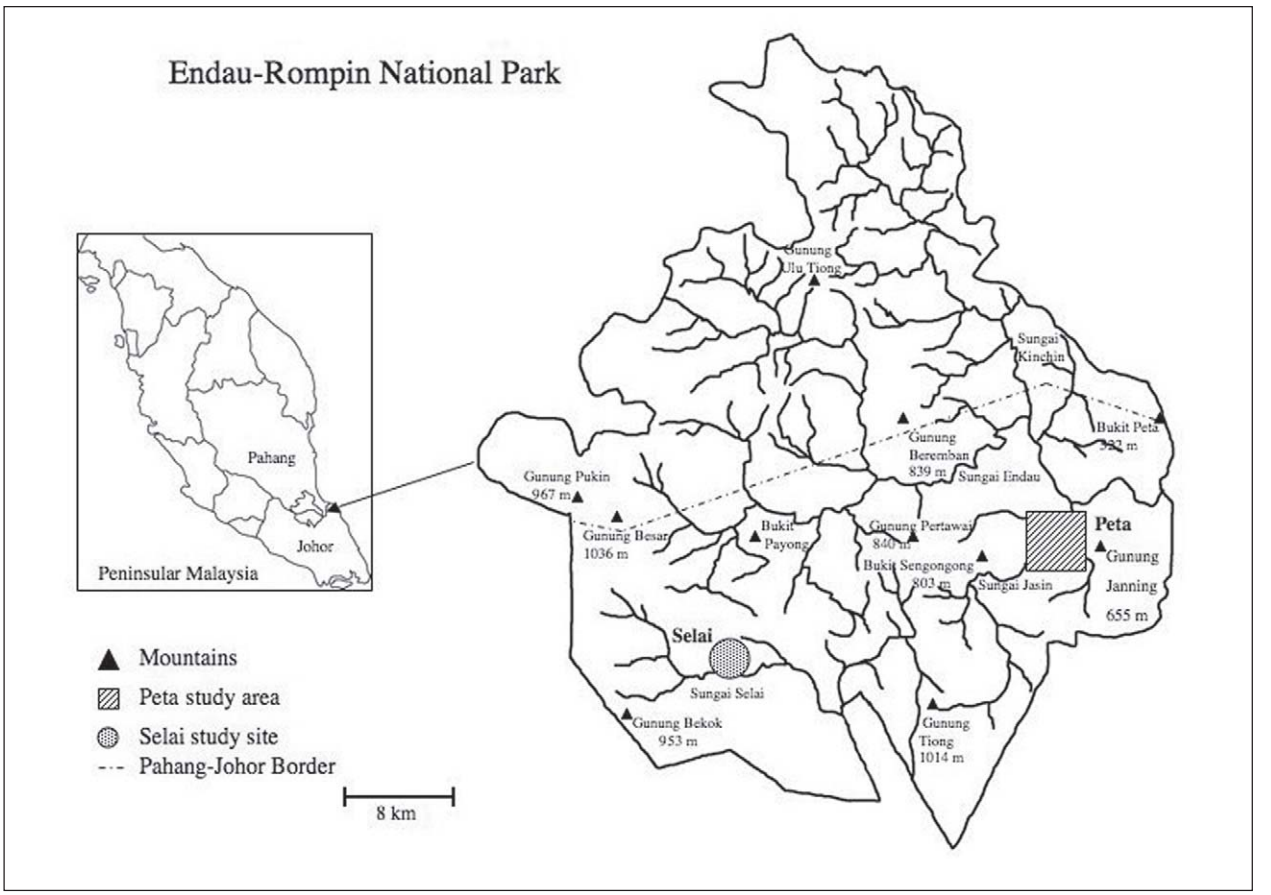

FIG. 1. Location of the Peta and Selai study sites, Johor, West Malaysia.

Rana nicobarensis (Stoliczka, 1870). (Fig. 5). Peta; Visitor center, 25 August, LSUHC 7624.

Testudines

Dogania subplana (Geoffroy Saint-Hillaire, 1809). Selai; Lubuk Merekek, Sungai Selai, 4 September 2006, LSUDPC 2619–29.

Manouria emys Schlegel & Müller, 1844. Selai, LSUDPC 2018. Photograph provided by park staff.

Squamata (Lizards)

Draco maximus Boulenger, 1893. (Fig. 6). Selai; Lubuk Tapah, 1 September 2006, LSUHC 8206.

Gonocephalus abbotti Cochran, 1922. (Fig. 7). Peta; NERC, 26 August 2005, LSUHC 7647. Sungai Semawak, 27 August 2005, LSUHC 7682. Selai; Lubuk Tapah, 31 August 2006, LSUHC 8172. These records represent a southern range extension of approximately 450 km.

Aeluroscalabotes felinus (Günther, 1864). (Fig. 8). Selai; Lubuk Tapah, 2 September 2006, LSUHC 8194.

Cnemaspis kendallii (Gray 1845). Peta; Sungai Semawak, 27 August 2005, LSUHC 7691. Selai; Lubuk Tapah, 30, 31 August and 2 and 4 September 2006, LSUHC 8122, 8210, 8126, 8191.

Gehyra mutilata (Wiegmann, 1834). Peta; Sungai Kawal. 28 August 2005, LSUDPC 1357. Selai; Lubuk Tapah, 2 September 2006, LSUHC 8187.

Hemidactylus craspedotus (Mocquard, 1890). Selai; Lubuk Merekek, 5 September 2006, LSUHC 8230.

Hemidactylus frenatus (Duméril & Bibron, 1836). Peta; Visitor Center. 25 August 2005, LSUHC 7645–46.

Hemidactylus platyurus (Schneider, 1792: 30). Peta; Visitor center, 25 August, LSUHC 7643–7644.

Hemiphyllodactylus typus (Bleeker, 1860). Peta. LSUDPC 1002–04. Photograph provided by park staff.

Ptychozoon kuhli Stejneger, 1902. Peta; Visitor Center, 27 and 30 August 2005, LSUHC 7640, 7716, respectively.

Dasia grisea (Gray, 1845). Selai; LSUPDC 1947–48. Photograph provided by park staff.

FIGS. 2–5, Opposite page, left column, from top to bottom. All photos by PLW. FIG. 2. *Ansonia endauensis* (ZRC 1.11555) from Peta, Sungai Kawal. FIG. 3. *Micryletta inornata* (LSUHC 7626) from the NERC. FIG. 4. *Limnonectes plicatellus* (LSUHC 8175) from Selai, Sungai Ketiau Padi. FIG. 5. *Rana nicobarensis* (LSUHC 7624) from Peta, Visitor Center.

FIGS. 6–8, Opposite page, right column, from top to bottom. All photos by PLW. FIG. 6. *Draco maximus* (LSUHC 8206) from Selai, Lubuk Tapah. FIG. 7. *Gonocephalus abbotti* (LSUHC 7647) near the NERC. FIG. 8. *Aeluroscalabotes felinus* (LSUHC 8194) from Selai, Lubuk Tapah.

Lipinia vittigera (Boulenger, 1894). Selai; Lubuk Merekek, 5 September 2006, LSUHC 8211.

Sphenomorphus scotophilus (Boulenger, 1900). Peta; Sungai Kawal, 28 August 2005, LSUHC 7688. Selai; Lubuk Merekek, 3 September 2006, LSUHC 8199.

Squamata (Snakes)

Ahaetulla facsiolata (Fischer, 1885). Peta: LSUHC 7697, found in collection at NERC with no data.

Ahaetulla mycterizans (Linneaus, 1758). Peta; Sungai Kawal, 26 August 2005, LSUHC 7680. Selai; Lubuk Merekek, 4 September 2006, LSUHC 8224.

Boiga drapiezii (Boie, 1872). (Fig. 9). Selai; Trail to Lubuk Tapah, 31 August and 2 September 2006, LSUHC 8143, 8192, respectively. Lubuk Tapah, 31 August 2006, LSUHC 8157.

Boiga nigriceps (Günther, 1863). (Fig. 10). Selai; Lubuk Merkek, 30 August 2006, LSUHC 8134, Trail to Lubuk Tapah, 31 August 2006, LSUHC 8142, Lubuk Tapah, 3 September 2006, LSUHC 8201.

Boiga jaspidea (Duméril, Duméril & Bibron, 1854). (Fig. 11). Peta; On road to Sungai Kawal, 25 August 2005, LSUHC 7679.

Calamaria lumbricoidea Boie, 1827. Peta; photographed provided by park staff. LSUDPC 1940.

Chrysopelea pelias (Boie, 1827). Peta; found in collection at NERC with no data, LSUHC 7696.

Coelognathus flavolineata (Schlegel, 1873). Selai; LSUDPC 2829. Photograph provided by park staff.

Dendrelaphis caudolineatus (Gray, 1830–1835). Selai; Lubuk Merekek, 5 September 2006, LSUHC 8225–26.

Dryocalamus subannulatus (Duméril, Bibron & (Duméril, 1854). Peta; Sungai Semawak, 27 August 2005, LSUHC 7661. Selai; Lubuk Merekek, 30 August 2006, LSUHC 8136.

Lycodon effraenis (Cantor, 1847). (Fig. 12). Peta; Sungai Semawak, 31 August 2005, LSUHC 7734.

Macrocalamus sp. Peta; LSUDPC 2830–31. No data. Photograph provided by park staff.

Oligodon purpurascens (Schlegel, 1837). (Fig. 13). Selai; on trail to Kuala Marong, August 30, 2005, LSUHC 7715.

Orthriophis taeniurus (Cope, 1861). Peta. LSUDPC 1005. No data. Photograph provided by park staff.

Pareas margaritophorus Jan, 1866. Peta; Bekok, photographed provided by park staff, LSUDPC 1078–79.

Pseudorabdion longiceps (Cantor, 1847). Peta; Visitor Center, 25 August 2005, LSUHC 7602.

Ptyas carinata (Günther, 1858). Peta; Sungai Semawak, 31 August 2005, LSUHC 7731. Selai; Lubuk Tapah, 31 August 200, LSUHC 8173.

Ptyas fusca (Günther, 1858). Peta; Sungai Semawak, 26 August 2005, LSUHC 7723.

Xenodermus javanicus Reinhardt 1836. Peta; LSUDPC 2032. No data. Photograph provided by park staff.

Calliophis bivirgatus (Boie, 1827). (Fig. 14). Peta; NERC 50716, no data. Photograph provided by park staff.

Parias hageni (Lidth De Jeude, 1886). (Fig. 15). Peta; NERC July 2006, LSUHC 8193.

Parias sumatranus (Raffles, 1882). Selai; LSUDPC 1971. Photograph provided by park staff.

Popeia fucata (Vogel, David & Pauwels, 2004). Peta. NERC 50704, 50748, no data. Photograph provided by park staff.

Trimeresurus wiroti (Trutnau, 1981). (Fig. 16). Peta; LSUDPC 952, no data. Photograph provided by park staff.

Discussion.—Daicus and Hashim (2004) reported both *Pelophryne signata* and *Pelophryne brevipes* as being present although only *P. brevipes* occurs in Peninsular Malaysia (Inger 1966). Also reported by Daicus and Hashim (2004) was *Ansonia leptopus*. Unfortunately, the specimen was released and no voucher photograph was taken. Given that *A. leptopus* is restricted to Borneo (Wood et al. 2008) it is likely the specimen was confused with *A. endauensis*. Daicus and Hashim (2004) reported *Rana signata* which we recognize here as *R. picturata* (*fide* Brown and Guttman 2002). *Typhlops diardii* was also reported (Daicus and Hashim 2004) although according to Wallach (2001) *T. diardii* is only found in NE Pakistan, N India, Nepal, Bangladesh, Myammar, Thailand, Laos, Vietnam, and China. This species is easily confused with *Typhlops muelleri* whose presence in the park had previously been reported (Daicus and Hashim 2004).

Kiew (1987) reported *Ansonia malayana* from Endau-Rompin, however there is no voucher specimen. We believe it is unlikely that this montane species, known no further south than Bukit Larut (Grismer 2006; Inger 1960), would not occur in a southern, lowland forest. It is our hypothesis that Kiew (1987) actually collected *A. endauensis*, a species that is superficially very similar to *A. malayana* (Grismer 2006a, b). Kiew (1987) also reported a specimen he referred to as *Microhyla* sp. Unfortunately the whereabouts of the specimen is unknown. It is likely, however, that it belonged to one of the six confirmed species of *Microhyla* known from Endau-Rompin (Table 1) that are often confused with one another.

Lim (1989) reported *Ichthyophis glutinosus* from Endau-Rompin. In light of the current taxonomic problems within the Ichthyophiidae in general and *Ichthyophis* (Gower et al. 2002; Grismer et al. 2006) in particular, it is difficult to accord any individual specimen to a particular species with any degree of confidence. Therefore, we follow Kiew (1987) in recognizing only

Ichthyophis sp.

Photographs were provided to us by park staff of what we believe is an undescribed species of *Macrocalamus* (LSUDPC 2830–31) based on the head not being distinct from the neck. This genus is currently represented by more northerly montane species and thus, this specimen is not only a southern range extension of approximately 180 km for *Macrocalamus* but the first specimen to be found in a lowland forest which represents a significant ecological departure as well (David and Pauwels 2004).

The new records reported here bring the total number of confirmed species of amphibians and reptiles in the park to 140 (1 caecilian, 51 frogs, 6 turtles, 39 lizards, and 43 snakes), representing an increase in diversity of 33% since Daicus and Hashim (2004) (Table 1). More importantly, these new records clearly underscore the understudied nature of the herpetofauna despite the many surveys that have been conducted (Bhaarathyraja 2006; Diacus and Hashim 2004; Kiew 1987; Lim 1989; Norhayati et al. 2004a,b). Additionally, the discovery of two new species of frogs, *Ansonia endauensis*, Grismer, 2006 and *Ingerophrynus gollum*, Grismer, 2007, the rediscovery of the gecko *Cyrtodactylus sworderi* (Smith, 1925; Grismer et al. 2007), and the discovery of *C. semenanjungensis* Grismer and Leong, 2005 just outside the eastern boundary of the park exemplify the need for continued systematic field work. The same argument could be made for the lowland rainforests of the entire state of Johor. Large portions of this unique section of the southern Malay Peninsula are being con-

verted into oil palm and rubber tree plantations with extensive tracts reaching deep into Endau-Rompin (authors, pers. obs., 2006).

Acknowledgments.—We thank Chan Kin Onn, Daicus M. Belabut, Sumen Govendasamy, Rick Gregory, Thomas Szutz, Bradely Jones, and the staff of the Johor National Park at Peta and Selai for assistance in the field. We would also like to thank Mr. Chew Keng Lin for many valuable photographs of several species. The Economic Planning Unit, Prime Minister's Department issued a research pass 40/2001/1955.1105 to LLG. This research was supported in part by a College of Arts and Sciences Research Grant to

Richard and Patricia Bartlett have been busy over the last decade or so. The sheer volume of work is impressive. In addition to the three volumes reviewed here, they coauthored a series of herpetoculture books, each about 50 pages long: three came out in 1999 (all on lizards), four in 2000 (two on frogs and two on snakes), six in 2001 (one on frogs, four on lizards, and one on snakes), one each in 2003 (Poison Dart Frogs) and 2004 (Box Turtles), and three in 2005 (all on snakes). The Bartletts are not newcomers to the field-guide scene either, having published texts about Florida (1998), Texas (1999), the western US (2000), and the Amazon (2003).

The current contributions share a consistent and attractive look, style, and geographic region, but focus on different taxonomic groups. Each offers a brief introduction (about 10 pages); species accounts (about 300 pages); a glossary and a list of additional readings (about four pages each); and an index (about six pages). The greatly similar introductions include information on the use of each book, comments on taxonomy, advice on captive care, some information on typical habitats, and illustrated keys to families. Contrary to what one might expect from authors who have heavily focused on the pet trade, the emphasis here is on conservation. There is discussion of declining species, loss of habitats, and the impacts of invasive species. The authors unambiguously advise against releasing animals in the wild and strongly advocate responsible herpetoculture.

Species accounts tend to be brief, ranging from less than a page to several pages. A nice feature is that the growing number of introduced species is also included, a valuable addition in many places, especially Florida. Each account includes the common and scientific name, both of which mostly follow Crother (2000). Purists may find this annoying, as there have been many proposed changes since then, but I suspect most readers, as the authors intended, will find it a relief to face familiar names. Occasionally, however, they are inconsistent. For example, soft-shelled turtles are all *Apalone* in the species accounts but *Trionyx* in the illustrations of snouts and shells. A range map and at least one photograph are also provided. As the authors point out, "[a]ll species and subspecies and several of the naturally occurring intergrades are pictured. There is no other field guide currently available that provides this important identification tool." Taxa with multiple color forms have multiple pictures, and occasionally this seems to get out of hand, as with the melanistic copperhead illustrated on p 288 (here and below, page numbers refer to the taxon-appropriate book). This appears intended to appeal to the hobbyist, particularly the one interested in the husbandry of unusual color morphs or trying to fill a life-list. Overall, however, this is a useful feature, and my copy of their Texas book is well-thumbed. Pictures are large, typically 1/3 of a page, and – like the distribution maps – are included within the text, rather than in a separate section as in some previous guides. Most pictures are quite good, but the quality varies. Frog pictures tend to be a bit smaller and are sometimes too dark, lacking in contrast, or out-of-focus to be really useful. This is the case with *Bufo americanus charlesithi* (p 17), *Acris c. crepitans* (p 37), *Hyla avivoca ogechiensis* (p 45), and *Rhinophrynus dorsalis* (p 116), for example. Such problems are less common in the other two books but they nonetheless occur, as with the fuzzy picture of *Acrochordus javanicus* (p 18 of the snake book) and *Anolis distichus* (p 243 of the final book), and the poorly contrasted pictures of *Anolis sagrei* and *A. cristatellus* (p 241). In addition to the all-color photographs, black-and-white drawings are occasionally provided (for example, a collared lizard on p 185 or the two salamander species on pages 118-119). These could have been left out, in my opinion, as they contribute little. Serviceable line drawings are used, often in the keys and occasionally elsewhere, to illustrate specific traits or distinguishing characters. Occasionally, as in the drawing of a pitviper head, the level of detail is insufficient: I'm not sure a naïve reader could tell the difference between the black dot representing the nostril and the equal-sized one representing the pit. The distribution maps are crisp and appropriately-sized for the area covered. Unlike some guides they include Canada, and sometimes pieces of Mexico. However, at least the map for the Mediterranean house gecko (p 170) does not include all the current Texas range. The authors may have been using dated sources: the 1987 edition of Dixon's book is referenced, rather than the second edition, published in 2000. In a similar vein, the work of Wilson and Porras (1983) appears in the citations, rather than the more recent Meshaka et al. (2004).

The text which follows offers brief coverage of range and abundance, size, and habitat. Snakes also get an entry on "disposition" and, if venomous, toxicity. Little information on natural history is provided, with most of the text focusing on identifying features. Many of those would require the animal to be in the hand to be discerned, however. Occasionally, a box contains the story of a memorable encounter with the species, printed in different font to indicate its less formal nature. At times, the authors use technical terms that are not given in the glossary (for example, "nuptial" and "distal" in the account of *Agama agama*). At times they use words that do not seem appropriate for the likely audience (e.g., "Lilliputian" [not capitalized for some reason] in the description of the genus *Sphaerodactylus*, "irascible" in describing the Prairie Rattlesnake). Unfortunately, the first paragraph of the preface to the first book I picked up (the amphibian volume) had a problem that is far too common in the age of electronic spellcheckers: the word "know" seems to have been lost, leaving the sentence "But we do that…" rather cryptic. However, I did not find other places with such problems. The index is comprehensive for common and scientific names.

In a review of an Arizona field-guide, Lamb (2007) recently shared a longing for the single-volume "indispensable little green book" such as Conant and Collins (1991) because of its "economy and ergonomic form." Alas, portability and natural history detail were sacrificed here for pictorial comprehensiveness, large font, and well-spaced text. These features, as well as the embedding of the pictures and range maps, and the affordable pricing, make the three books more attractive and easier to read. However, the combined size also makes them less useful as field guides. I can imagine these volumes sitting on the shelf of hobbyists, but I do not foresee well-used copies in the glove-compartments of many professionals.

e-mail: duellman@ku.edu

With facing pages in English and Spanish and more than 150 color photographs this outstanding book brings to life the Glassfrogs (Centrolenidae) of Costa Rica in a manner that sets an example for the treatment of any group of organisms. The author spent nearly a decade observing, rearing, and photographing Glassfrogs in Costa Rica. In so doing he gathered an enormous amount of data that is the basis for this book that greatly expands the accounts of centrolenid frogs given by Savage (2002).

This paper-bound book of 299 pages (15 × 22.8 cm) is printed on high-quality glossy paper. The first 79 pages contain a brief forward by Jay M. Savage, introductory material, an account of the taxonomic history of the family, and a summary of behavior and ecology of Costa Rican centrolenids. In the introduction, Kubicki thoroughly describes the external morphology of Glassfrogs and illustrates their principal characters. In the section on behavior and ecology, he summarizes information on habitat, diversity, activity, feeding, reproduction, male-male combat, and embryonic and larval development. Throughout these sections he has added his extensive observations to what was known previously (in most cases, very little), thereby providing a comprehensive review of the biology of Costa Rican centrolenids.

The major part of the book (201 pages) is devoted to accounts of each of the 13 species of Costa Rican centrolenid frogs. Each account contains sections on: Holotype, Type Locality, Synonymy and chronological history of the nomenclature, Common name, Etymology, Species group, Description, Similar species, Sex determination, Distribution, Natural history, Call, Calling position, Egg masses and larvae, and Abundance. Although data on morphology used in the descriptions, comparisons, and sex determination are common in recent literature on Glassfrogs, most of the information in the sections on natural history, behavior, and development is new. In the accounts there are 13 distribution maps

and 146 excellent color photographs, including 13 photographs of living tadpoles and 22 photographs of clutches of eggs. The account of each species contains no fewer than five photographs of living frogs, including ventral views, pairs in amplexus, and males in combat. Although the calls of each species are described in detail, sonograms and wave forms are not presented.

Kubicki listed 16 species of centrolenid frogs in Central America and noted that all but three occur in Costa Rica. The percentage of Costa Rican Glassfrogs increased with the placement of the Honduran *Hylalinobatrachium cardiacalyptum* and *H. crybetes* in the synonymies of *H. chirripo* and *H. colymbiphyllum*, respectively, by Cisneros-Heredia and McDiarmid (2007). Thus, the only species of Glassfrog extralimital to Costa Rica in Central America is *Hyalinobatrachium aureoguttatum*, a South American species that enters Darién in Panama. There are some minor discrepancies regarding the taxonomy: (1) *ilex* and *prosoblepon* are placed in the genus *Centrolenella*, which is listed as a junior synonym of *Centrolene* by Frost (2007); and (2) *pulveratum* is placed in *Hyalinobatrachium*, whereas the species was placed in *Cochranella* by Cisneros-Heredia and McDiarmid (2006).

Kubicki's "Glass frogs" contains much more information on natural history and has far superior color illustrations than two other recent publications dealing with centrolenid frogs of Ecuador (Cisneros-Heredia and McDiarmid 2007) and Venezuela (Señaris and Ayarzagüena 2005). "Glass frogs" is just one of many outstanding publications produced by the Costa Rican Instituto Nacional de Biodiversidad, an institution that has set high standards for gathering and disseminating data on national biodiversity. Both the author and the institute deserve international accolades.

e-mail: jesse.grismer@villanova.edu

A Field Guide to the Amphibians and Reptiles of Bali is a detailed overview of the 114 species of amphibians and reptiles known from this tropical island. Bali is a relatively small Indonesian island (128 × 76 km) located 5 km east of Java and 45 km west of Lombok. It is of biogeographical interest in that it lies immediately west of Wallace's Line and represents the most southeasterly extent of the range of many taxa. This book presents the most up-to-date list of amphibians since Iskandar (1998) and the first list of reptiles for the island since Brongersma (1934). The author states that the purpose of the book is to provide an easy identification for any species of the island's amphibians or reptiles. Was this goal accomplished? In many aspects it was, and anyone could use this book to identify most of the herpetofauna of Bali, but it may have fallen short in some areas.

In the introduction the author provides a useful map, and gives an overview of some of the classic works and more recent book length treatments that have been published on southeast Asian herpetology. In Chapter 2, "Making an Identification," the author does a good job in discussing how to make an identification with a specimen in hand and provides diagnostic characters to look for if the specimen was not captured but only observed. This chapter is accompanied by clear and precisely labeled illustrations of frog and tadpole anatomy, turtle shell morphology, and lizard and snake head scalation (lateral, dorsal, and ventral views), and instructions on how to perform certain scale counts. Chapter 3, "Explanation of the species Accounts," provides instruction on how to use the species accounts along with descriptions of the subsections within the species accounts. Chapter 4, "Environment of Bali," gives background on the ecological and geological make up of the island and a detailed description of the different types of habitats, including a list of species that are generally associated with each habitat. This chapter also discusses human impact on the island's natural vegetation.

Chapter 5, "An Overview of Amphibian and Reptile Fauna," is a discussion concerning the evolutionary origins of the fauna of Bali as a mixture of southeast Asian and Papuan elements. Here

the author discusses the diversity of Bali compared to that of the surrounding islands and provides a general overview of the different types of lizard and snake ecologies observed on Bali. Chapter 6, "Traditional Uses and the Turtle Trade," is a discussion of the medicinal and commercial uses of the amphibian and reptile fauna. The majority of this chapter is concerned with the use of sea turtles as a food source and documents the growth and decline of this industry. It includes some disturbing anecdotes detailing the harsh treatment of these animals after they have been sold in the marketplace. In chapter 7 "First Aid for Snakebites," the author describes the types of bites one could receive from the different species of venomous snakes (cobras, kraits, pitvipers, and sea snakes) on Bali and the procedures to follow in case of a bite.

The following chapter, "Amphibians, Class Amphibia," begins with a key to all the frog species and their tadpoles; one in English and the other in Bahasa Indonesia. Each is accompanied by several diagrams of frog and tadpole characters useful for identifying certain species. This is followed by the species accounts for frogs. The species accounts consist of one or two small (8.5 × 5.8 cm) photographs of the species and a short (maximum one page) account with four sections. The first, "Description," is an adequate overview of the color pattern, snout–vent length, total length, tadpole morphology, and morphological variation within the species. The next section is "Habitat," describing the type of habitat and microhabitat in which each species occurs as well as its elevated range. Following this is "Biology," which discusses natural history, including activity times, call descriptions, and where tadpoles can be found. The last section, "Distribution," lists the major islands and mainland countries of each species' range throughout southeast Asia. One point of possible contention is that Iskandar (1998) records *Occidozyga lima* on Bali, where here and in Frost et al. (2006), *O. laevis* is the only species of *Occidozyga* recorded.

Chapter 9, "Reptiles, Class Reptilia," is organized similarly to the previous chapter. Each section (turtles, lizards, and snakes) has English and Bahasa Indonesia keys followed by illustrations of head scalation and other relevant morphological characters and species accounts mirror those for amphibians. The main difference between the treatments of the three reptile groups is in the emphasis on diet for snakes. In the appendix, there is a section called "Species Not Yet Recorded on Bali" in which species accounts are given for several species which the author believes have a high probability of being discovered on Bali due to their presence on nearby islands or their widespread distribution in the region. This is an interesting section but the inclusion of these species along with the confirmed species makes the keys unnecessarily long. Following the appendix is a glossary of terms used for describing amphibian and reptile morphology and certain terms in Bahasa Indonesia.

This book does have some shortcomings. The quality of photography makes it difficult to positively identify roughly 10% of the species (e.g., *Occidozyga laevis* [Plate 31], *Rana chalaconota* [Plate 35], *Rana nicobariensis* [Plate 39], *Eutropis rugifera* [Plate 77], *Sphenomorphus temminckii* [Plate 82], *Boiga cynodon* [Plate 94], *Enhydris plumbea* [Plate 106], *Gongylosoma balioderium* [Plate 108], and *Rhabdophis chrysargos* [Plate 123]). Many of the photographs are of individuals from outside of Bali. This is normally not a significant concern if the specimen was collected from an adjacent region, but in some cases the specimen photographed is from Australia, Sulawesi, or China where populations may look significantly different. An unfortunate oversight is the lack of a figure showing the details of foot morphology that are diagnostic for many species of reptiles and amphibians. The Literature Cited is divided into categories with citations listed under the category in which each was referenced in the text. This is a bit awkward as the reader must search in several places to locate any particular reference. Finally, without explanation the author chose to recognize recent taxonomic revisions for the Scincidae (*Mabuya*; Mausfeld and Schmitz 2005) and the ratsnakes (*Elaphe*; Utiger et al. 2002) but not for *Trimeresurus* (Malhorta and Thorpe 2004), or the paraphyletic genus *Rana* (Dubois 1987, 1992; Frost et al. 2006).

These drawbacks aside, this book is an informative field guide to most of the amphibians and reptiles of Bali and is a great stepping-stone for future work. It is also an indespensible piece of literature for anyone interested in southeast Asian herpetology in general.

PUBLICATIONS RECEIVED

***Chamaeleo calyptratus*, the Yemen Chameleon,** Second Edition, by Wolfgang Schmidt. 2007. Natur und Tier-Verlag, Münster, Germany (www.ms-verlag.de). 96 pp. Hardcover. € 18.50 (approx. US $27.00). ISBN 978-3-86659-036-6.

This is an English translation of the original German language popular book on the biology and husbandry of *Chamaeleo calyptratus*, a large and charismatic chameleon in which males bear a huge casque. These impressive lizards have become relatively common in the private collections of terrarium keepers and this book was written to provide guidance to prospective owners, based on the author's years of experience with Yemen Chameleons. Basic information is provided about the evolution of chameleons, the habitat of the Yemen Chameleon, and distinctive features of this and other chameleons (color and color change, casque, tail prehension, independently mobile eyes, tongue protrusion). Advice is provided about selecting and sexing Yemen Chameleons and mating behaviors, copulation, and oviposition are discussed and illustrated by color photos of captive animals. Much of the text is devoted to information about housing individuals of this species (they should be kept alone and provided with good ventilation and adequate possibilities for climbing), feeding them (diet should be varied and vitamin-enriched), and regulating their environment (temperatures should reflect those seen in nature, with both diel and seasonal variation; Yemen Chameleons are particularly suitable for limited free-ranging activity in outdoor enclosures). The book concludes with brief comments on disease and other veterinary concerns and a 66-entry bibliography. This small book serves as a concise guide to *Chamaeleo calyptratus* and its captive care and breeding and is recommended reading for anyone considering maintaining this species in captivity. Unfortunately, most of the references to further sources of information are specific to Germany and this English edition suffers from some instances of awkward translation and some typographical errors. Nonetheless, the book contains a great deal of information gathered over the many years that this species has been successfully bred in Europe and the 75 color photographs and non-technical text make it accessible to a wide audience.

Amphibien an einem Stillgewässer in Peru mit einer illustrierten Checklist der Amphibien und reptilien des unteren Río Llullapichis, by Andreas Schlüter. 2005. Edition Chimaira, Frankfurt am Main, Germany (www.chimaira.de). 347 pp. Hardcover. € 49.80 (approx. US $74.00). ISBN 3-930612-51-8.

This book stems from the doctoral work conducted by Andreas Schlüter at a site on the lower Río Llullapichis in Amazonian Peru. Although the author has published many of his findings in the 30 years since the field work was initiated, this volume represents a comprehensive, if much belated, summary of his study as a whole, which examines the biotic and abiotic causes for the comparatively low frog diversity in the study site—a shaded pond in montane rainforest. The entire metazoan fauna of the pond is characterized and 71 anuran species were identified at the site, 30 utilizing the pond itself. Species accounts are presented for each of these 30 frogs. The information summarized includes synonymy, geographic distribution, size, recognition characteristics, breeding call, diet, reproductive mode and development, activity period, relationship to the pond, and autecological description. These accounts are variably accompanied by line drawings of a selected specimen, a sonogram, distribution map, and black and white photograph(s) of adults, larvae or eggs. These are supplemented by a section of 100 half page color photos illustrating the amphibians of the pond and remaining study site. Niche segregation of anuran mating calls is considered and a remarkable once-a-year mass concert is described and analyzed with respect to its chorus structure. The book also considers responses to predators, the adaptations of eggs, and the ethology and spatial niche partitioning of larvae. A checklist of the herpetofauna of the lower Río Llullapichis is provided and 65 color photos illustrate the reptiles of the area, which are otherwise peripheral to the work as a whole. The book concludes with a literature cited with about 350 entries. Despite the fact that the dissertation upon which this book is based was completed in 1984, the data presented remain valuable, particularly in a comparative light, as other anuran communities in Amazonia have subsequently been investigated. This book will certainly be of interest to amphibian ecologists and ethologists as well as herpetologists with general interests in Amazonia. Short English and Spanish abstracts provide an overview for non-German speakers.

Timber Rattlesnakes in Vermont and New York: Biology, History, and the Fate of an Endangered Species, by Jon Furman. 2008. University Press of New England, Lebanon, New Hampshire (www.upne.com). 224 pp., 12 color illustrations, softcover. US $24.95. ISBN 978-1-58465-656-2.

This highly readable book, targeting a non-professional audience, details the natural history and conservation status of *Crotalus horrridus* near the northeastern extreme of its historical range. In this region, Timber Rattlesnakes are highly endangered, in large part due to a long history of bounty hunting, which Furman covers in fascinating, albeit disturbing, detail. A number of bounty hunters are profiled, and some agreed to be interviewed for the book. Recent and ongoing conservation conflicts are presented, as well as future prospects. The author, an "accomplished naturalist" (from the press release), benefited from collaborations with field researchers William Brown, Marty Martin, and Randy Stechert; their cooperation ensured that the biological information presented was accurate and current. This book is likely to appeal to a broad audience of herpetologists, conservationists, and readers with an interest in wildlife of the northeastern U.S.

Inseparable Friends in Life and Death, the Life and Work of Heinrich Kuhl (1797–1821) and Johan Conrad van Hasselt (1797–1823), Students of Prof. Theodorus van Swinderen, by Charles Klaver. 2007. Barkhuis, Groningen, The Netherlands (www.barkhuis.nl). ix + 105 pp. Softcover. € 25,00 (approx. US

$37.00). ISBN 978-90-77922-316.

The history of herpetology is rife with personalities who made major contributions during very short lives. Among the most tragic of such deaths were those of two young friends who had met at the University of Groningen in the Netherlands, Heinrich Kuhl and Johan Conrad von Hasselt. Both were accomplished and respected zoologists by the age of 20 and were personally acquainted with the leadings scientists of the day, including Cuvier, Lichtenstein, and Temminck. In 1820 both men were appointed as delegates of the Natuurkundige Commissie voor Nederlandsch Indië (Commission for the Study of the Natural Sciences of the Netherlands East Indies) and departed for Java, where Kuhl died in September 1821 and Van Hasselt two years later. In their brief period of collecting, Kuhl and van Hasselt sent thousands of specimens back to Europe, among them 300 amphibians and reptiles of 90 species. Many were new and were described by them in published letters to colleagues in Europe. Another herpetological project of Kuhl's, completed before his departure for Asia, but never published, was the identification of the herpetological illustrations in Seba's *Thesaurus*.

Charles Klaver's biography of Kuhl and Van Hasselt provides a glimpse of the promising careers of the two men, who are unknown to most herpetologists. Although short, the biography and its detailed endnotes, both of which are fully indexed, are a wealth of information about Kuhl and Van Hasselt, their achievements, and the European zoological community in the early 19th century. A bibliography of the 66 publications of the two (1817–1845) is an invaluable tool, as the works of Kuhl and Van Hasselt are among the most miscited in systematic herpetology. A bibliography of more than 230 entries supports the biography. An appendix lists the valid names proposed by Kuhl and Van Hasselt (101 genera, species, and subspecies in all major tetrapod groups, as well as teleost fish and mollusks) and those zoological taxa named in their honor (31). A second appendix is a synopsis of the nomenclatural status of the herpetological names authored by Kuhl and Van Hasselt in their published letters from Java. This includes 32 names (including errors, nomina nuda, junior synonyms and valid names), among them such familiar taxa as *Megophrys*, *Rhacophorus*, *Homalopsis*, and *Ptychozoon*. The book is illustrated by 16 figures (four herpetological) representing portraits, animals, and images of manuscripts and published works.

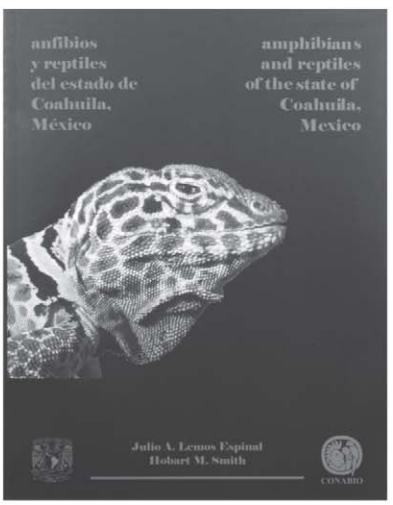
Inseparable Friends is highly recommended to anyone with an interest in the history of zoology or in the fauna of the Indonesian region. However, it provides particular insight into the herpetological aspects of Kuhl and Van Hasselt's careers (in part because the author's first career was as a chameleon systematist).

Die Nilweichschildkröte *Trionyx triunguis*, by Dieter Gramentz. 2005. Edition Chimaira, Frankfurt am Main, Germany (www.chimaira.de). 166 pp. Hardcover. € 44,80 (approx. US $66.00). ISBN 3-930612-41-0.

This is a German language monographic work on the trionychid turtle *Trionyx triunguis*. It includes a synonymy, list of vernacular names, phylogenetic tree, and an extensive section on morphology, including carapace and plastron size and proportion, osteology, and soft anatomy (largely drawn from the earlier works of Girgis). Coloration, blood chemistry, karyology and both sexual and ontogenetic variation are also reviewed. This large softshell turtle (to 85 cm or more carapace length) has a huge distributional range — from the eastern Mediterranean south along the Nile into East Africa and from Senegal to northern Namibia in West Africa. Most of the author's observations were derived from his own extensive field work in Gabon and especially in Turkey. As might be expected for a species with such a broad range, ecological and reproductive parameters are highly variable. Water bodies of all sizes, flow rates, depths, acidities, and salinities, from small lakes to the ocean are utilized by *T. triunguis*. Data are presented on reproductive parameters (timing, egg and clutch size, hatching success) for populations from Turkey and Gabon. Factors threatening the Turkish populations are considered in some detail. These include habitat destruction, accidental deaths caused by fishing nets and boat propellers, as well as intentional killings by those who perceive the turtles as pests. As of 2005 there were no effective measures of protection, and relict inland populations at Dalyan and Dalaman, Turkey (totaling only a few hundred individuals) were particularly imperiled.

Table and figure legends are given in both German and English and an extensive six page English summary is provided, providing English speakers with access to all of the author's major findings. The book is illustrated with 129 figures, 69 of them in color. Most of these are adequate, but a few (e.g., Figs. 83, 111) are not in focus. In addition to adults, juveniles, eggs, and habitats, photos show dead and damaged turtles reflecting negative human impact on Turkish populations of *T. triunguis*. Numerous graphs and tables present original data relating to activity, nesting, incubation, and other aspects of life history. The bibliography cites 136 references. There are occasional typographical errors in both the English (e.g., scull instead of skull, p. 50) and Latin technical terms (e.g., Opithoticum instead of Opisthoticum, p. 18) but otherwise the text is largely free of errors. This monograph will, of course, be of interest to cheloniophiles, but also to herpetologists and conservation biologists with special interests in Turkey.

A New Herpetological Circular from the Society for the Study of Amphibians and Reptiles
Herpetological Circular 37



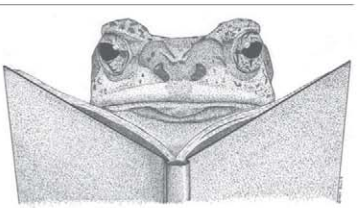
SCIENTIFIC AND STANDARD ENGLISH NAMES OF AMPHIBIANS AND REPTILES OF NORTH AMERICA NORTH OF MEXICO, WITH COMMENTS REGARDING CONFIDENCE IN OUR UNDERSTANDING

COMMITTEE ON STANDARD ENGLISH AND SCIENTIFIC NAMES

This is the official name list of American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. The list incorporates all taxonomic changes since the 2000 edition. This is a must for anyone working with North American herpetology. 84 pages. January 2008. ISBN 978-0-916984-74-8

Prices: Prepublication (SSAR members only)		After May 31, 2008	US $12.00
first copy -	US $8.00	USA Shipping : First copy	US $2.00
additional copies	US $6.00	Additional copies	US $1.00

Send orders to: Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158-0517, USA. Telephone / fax 801-562-2660; email: ssar@herplit.com. Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MasterCard (Account number and expiration date must be provided). SSAR membership details and a complete list of Society publications can be obtained on request from the Publications Secretary.



Amphibians & Reptiles
of the State of
Coahuila, Mexico
Julio A. Lemos Espinal & Hobart M. Smith

The most comprehensive text on the amphibians and reptiles of the state of Coahuila, Mexico. Contains taxonomic keys, in depth species descriptions, color photographs, gazetteer, dot distribution maps, and localities of collection. Complete text in both Spanish and English

Specifications: xii, 552 pages, 8½ x 11 inches. Paperback (ISBN: 970-9000-40-3) $90.00 + postage.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution or Natural History notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order form will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Central Michigan University, Department of Biology, 217 Brooks Hall, Mt. Pleasant, MI 48859, USA. Periodicals postage paid at Mt. Pleasant, MI 48859 and at additional mailing offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Allen Press, Inc., P.O. Box 1897, Lawrence, KS 66044, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Regarding missing or damaged issues, please notify *Herpetological Review*, Allen Press, Inc., P.O. Box 1897, Lawrence, KS 66044, USA (tel. 785/843-1234 or e-mail: herps@allenpress.com).

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 840		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

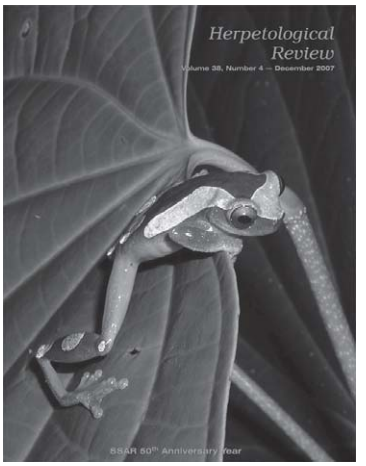
www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2008 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its newsjournal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

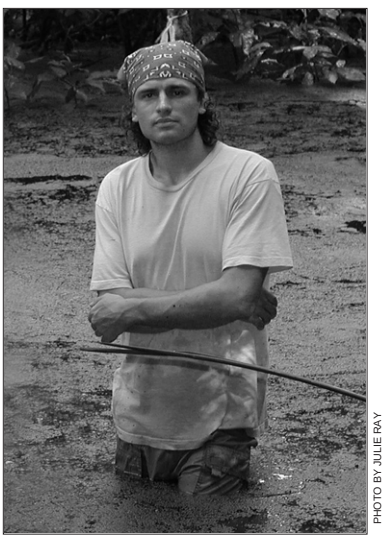


To join SSAR or to renew your membership, please visit the secure online Allen Press website:

http://timssnet.allenpress.com/ECOMSSAR/timssnet/common/tnt_frontpage.cfm

Future Annual Meetings

2008 — Montreal, Canada, 23–28 July (with ASIH, HL)
2009 — Portland, Oregon (with ASIH, HL)



About Our Cover: *Dendropsophus leucophyllatus*

The family Hylidae includes about 850 species of treefrogs with 3 subfamilies and 42 genera (Frost et al. 2006. Bulletin of the American Museum of Natural History 297:1–371). Over 150 species of hylids are known to occur in the tropical lowlands of South America, with many new species yet to be described. The diversity of Amazonian hylids can only be trumped by the intensity of their breeding choruses and spectacular array of color patterns. Body patterns range from the cryptic, leaf-like pattern of *Cruziohyla craspedopus* and *Hemiphractus proboscideus*, to the vibrant coloration of *Dendropsophus rhodopeplus* and *D. leucophyllatus*, the subject of our cover.

Dendropsophus leucophyllatus—formerly *Hyla leucophyllata* (see Faivovich et al. 2005. Bulletin of the American Museum of Natural History 94:1–294)—the Clown Treefrog, is a moderate-sized anuran distributed throughout the Amazon Basin. This species exhibits an impressive array of polymorphism throughout much of its range. Within a population, individuals can vary from the more common "clown pattern" pictured on our cover, to a highly reticulated pattern similar to that of a giraffe, or some intermediate combination of these two patterns. The variation in color pattern is so disparate that historically, individuals with the giraffe pattern were considered to be a separate species, *Hyla favosa*, and individuals with an intermediate pattern were thought to be hybrids. It was not until Titus et al. (1989. Herpetologica 45:17–23) determined that individuals with these three phenotypes exhibited high degrees of genetic similarities and constituted the same species.

Although the clown phase is by far the most commonly encountered form, all three phenotypes can be found together at permanent wetlands. During the rainy season males will call alone or in small clusters of 3–5 individuals perched together on a bush or leafy vegetation above the water (Duellman 2005. Cusco Amazónico. Cornell University Press, Ithaca, New York. pp. 215–218). In breeding aggregations with multiple clusters, males of one cluster will call in synchrony while the other clusters remain silent. Before these males finish calling, males from the next cluster will begin calling, followed in a similar fashion by the remaining clusters before the males of the first cluster will call again.

PHOTO BY JULIE RAY

Clint R.V. Otto recorded the cover image with an Olympus C-3000 Zoom digital camera using a Justrite Electric Head Lantern as a secondary light source. At night, this specimen had light yellow/orange colored extremities, but they turned dark orange the following day. Otto has taken two trips to Reserva Amazonica, a wildlife sanctuary in the Peruvian lowlands, to participate in a long-term amphibian monitoring project headed by Erik Wild. He currently works for the U.S. Geological Survey in Laurel, Maryland, and intends to enter a Ph.D. program in the near future.

SSAR BUSINESS

2007 Annual Meeting, St Louis, Missouri

The Annual Meeting of SSAR took place from 11–16 July 2007 at the Hyatt Regency Hotel in St Louis, Missouri. This was a very special meeting for our Society as it occurred during our 50th Anniversary Year. As has been the case since 2001, SSAR met jointly with members of the American Elasmobranch Society (AES), the American Society of Ichthyologists and Herpetologists (ASIH), and the Herpetologists' League (HL). Also in attendance were members of the Neotropical Ichthyological Society and the North American Native Fishes Association. The meeting was hosted by the St Louis University College of Arts and Sciences and Department of Biology with local hosts Richard Mayden (chair), Robert Aldridge, Nevin Aspinwall, Jason Knouft, and Robert Wood.

A total of 1060 herpetologists and ichthyologists from 26 countries (including Argentina, Costa Rica, Ecuador, Italy, Jamaica, Japan, Mexico, and New Zealand) attended the meeting. The international flavor of the meeting was reflected in a poster produced by SSAR that issued welcomes to all attendees in some 15 languages (Fig. 1). Most meeting participants were from the United States. Canada, Brazil, and Australia were the 2nd, 3rd, and 4th best represented countries, respectively. Just over 50% of those present were students, and around 570 papers and 300 posters were presented. SSAR, ASIH, HL, and AES each sponsored one symposium.

A Brief History of OHS / SSAR

Fifty years ago, two young herpetologists, Kraig Adler and Dave Dennis (then aged 16 and 17, respectively), founded The Ohio Herpetological Society (OHS). Although ASIH and HL were in existence in 1958, the early members of the OHS felt the need to form a regional society that would allow them to connect through a journal, a newsletter, and an annual meeting and field trip (Fig. 2). By the end of its first year, OHS boasted around 100 members (many from outside Ohio and a number from overseas) including Ron Brandon, Joe Collins, Roger Conant, Carl Gans, Carl Kauffeld, Laurence Klauber, Jack McCoy, Graham Netting, Marlin Perkins, Jim Peters, Clifford Pope, Chuck Shaw, and Bob Stebbins and had subscriptions from such institutions as the American Museum, the Museum of Comparative Zoology at Harvard University, and the British Museum (Nat. Hist.). In 1967, the OHS changed its name to the Society for the Study of Amphibians and Reptiles (SSAR). By 1972, membership had risen to 1,000. Four of the original members of OHS are still active, 42 individuals have been members for more than 40 years, and 335 individuals have been members for more than 25 years.

From its humble beginnings, SSAR has become an extraordinarily successful international Society. We now have over 2,300 active members from 60 countries. Twenty five percent of our members are students. We have multiple categories of membership—student, regular annual, plenary, sustaining, contributing, and patron. Our annual budget is in the hundreds of thousands of dollars and most of that is used to support our publication efforts. We publish seven series on a regular basis (*Catalogue of American Amphibians and Reptiles*, *Contributions to Herpetology*, *Facsimile Reprints in Herpetology*, *Herpetological Circulars*, *Herpetological Conservation*, *Herpetological Review*, and *Journal of Herpetology*; Fig. 3), more series than are published by any other vertebrate society in the world. *Journal of Herpetology* and *Herpetological Review* are both published four times a year and we are currently issuing volumes 41 and 38, respectively. This year for the first time, *Journal of Herpetology* is likely to receive over 300 manuscript submissions. The *Facsimile* series in particular has been very important in the growth of the Society. In

regards to this publication effort, Jay Savage in 1988 remarked "First, the uniqueness of this activity (not duplicated by any other society) gave SSAR a special identifying quality that legitimized the group as a serious scientific association. Second, it provided an unusual and valuable prerogative that aided in the recruitment of new members. Finally, income from sales…provided additional revenue that subsidized…the publication of the *Journal of Herpetology* and *Herpetological Review*. Under these circumstances one must attribute much of the growth and success of SSAR to this innovative publishing venture that contributes so much to the reputation and vitality of the society" (*Herpetological Review* 19:42–43). The Society has come a long way from the ditto machine used in the early OHS days!

A sizeable fraction of our budget is also used to directly support student research and attendance at our Annual Meeting. We present four awards at the Meeting for the best student papers (the Henri Seibert Award), seven awards for student research (Grants in Herpetology and the Dean Metter Award), 10 student travel awards, and an award for the best student paper published in the *Journal of Herpetology* (the Kennedy Award)

The Society has its roots in member, particularly student member, participation and has become what it is because of the efforts of many individuals over the years. Hundreds of members have served as Officers, Editors, Associate Editors, Chairs and members of committees, manuscript reviewers, judges of student papers (oral and published), symposium organizers, etc. Some have served extraordinarily long terms. Henri Seibert for example, served for 28 years in various capacities and, in addition to filling several offices (including President), Kraig Adler has served as editor of various publications for 50 years. Doug Taylor was Publications Secretary and Treasurer for 16 years, and Robert Hansen, Bob Aldridge, and Joe Collins served for 16, 14, and 13 years respectively in several positions.

Female herpetologists have had a strong presence in the Society. As president of SSAR in 1979, Margaret Stewart was the first woman to serve as president of one of the major herpetological societies. Since Meg's term, SSAR has had four other female Presidents (Linda Maxson, 1992, Lynn Houck, 1994, Janalee Caldwell, 2003–2004 and Robin Andrews, 2005–2006) and women have held both elected and appointed positions at all levels of the Society.

SSAR and OHS have long enjoyed a sizeable international membership, particularly of students, and this is clearly reflected in the proportion of overseas herpetologists at our Annual Meetings. We reserve a position on our Board for a non-U.S. member and this has been filled by, among others, Gustavo Casas-Andreu (Mexico), David Green (Canada), Tim Halliday (United Kingdom), Gabriela Parra Olea (Mexico), Rick Shine (Australia), and Richard Wassersug (Canada). David Green also served a term as President (2001–2002). One of the awards in our Grants-in-Herpetology Program is preferentially reserved for students from countries where herpetological research has historically been under-funded. We maintain an updated list of international funding opportunities on our website and we offer a manuscript review service for herpetologists for whom English is not their native language who require editorial assistance.

Our website (http://www.ssarherps.org/), started in 1995 by George Pisani, received 973,213 hits in the past 12 months. The website includes a copy of our Constitution, lists of past and present Officers, Editors, and Committee Chairs, information about our publications, a discussion forum, and useful information about careers in herpetology, grant opportunities, job posting, and our manuscript review service. It is regularly updated by our dedicated webmaster Zack Walker and now Raul Diaz.

SSAR's Annual Meetings have been a high point for the field of herpetology for many years. This year's meeting was no exception. In celebration of our 50th Anniversary, many members, particularly older members, who had not attended meetings for a number of years, were present. It wasn't just the younger members of the Society who were impressed by the "Who's Who" in Herpetology at the meeting!

Many individuals worked extremely hard to make this 50th Anniversary Meeting one to remember. The Society wishes to thank in particular the members of the 50th Anniversary Committee (Al Savitzky, chair, Bob Aldridge, Robin Andrews, Janalee Caldwell, Jonathan Losos, Roy McDiarmid, Henry Mushinsky, and Kirsten Nicholson) as well as Ronn Altig, Kraig Adler, Breck Bartholomew, David Dennis, and Jim Murphy. As a society we have much to celebrate and much to take pride in. We also have some significant challenges to face. Here's to anticipating that we have even more to celebrate when our 100th Anniversary rolls around.

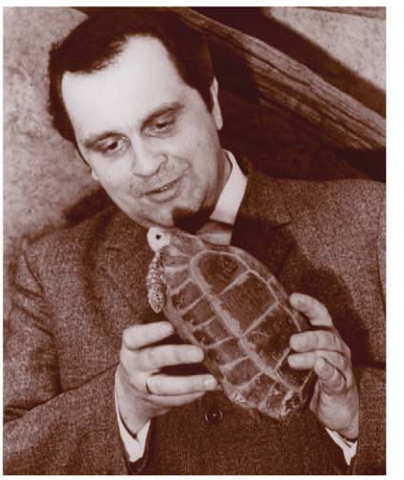
Annual Meeting, 2007

The Annual Meeting began officially on the morning of Thursday, July 12th with a welcome from Rick Mayden, chair of the Local Host Committee. Jeff Carrrier, President of AES, then introduced Jack Musick who spoke on "The Changing Face of Shark Research: 400 Million Years of Evolution and Four Decades of Shark Research." Jack was honored later during the meeting at a special retirement dinner. Plenary addresses were given by Darrell Frost, Immediate Past President of ASIH ("Progress and Controversy: Perspectives on the Last 40 years") and Marvalee Wake, The Herpetologists' League's Distinguished Herpetologist ("Eye of Newt and Toe of Frog: Herpetology in 21st Century Science"). Rick Mayden then presented Carl von Linné Awards for Outstanding Contributions in Herpetology and in Ichthyology to Darrell Frost and William Eschmeyer, respectively. As usual, group photographs followed the conclusion of the morning Plenary Session, and paper and poster presentations began after lunch.

The Joint Meeting Reception was held in the City Museum that evening. This Museum, which opened in 1997, was designed by the artist Bob Cassilly and is housed in the 600,000 ft^2 former International Shoe Company building. We were warned to dress appropriately as we would want to take advantage of the slides, tunnels, and various attractions. The warning was well heeded. The museum is hard to describe and photographs only begin to capture what an amazing and fun place it is. It has been called a "warehouse of adventure for people of all ages and a museum unlike any other." It contains an enchanted forest, secret caves and passageways, multiple slides, MonstroCity (two Saber 40 aircraft fuselages, a fire engine, a castle turret, a 25-foot tall cupola and several 4-foot wide wrought-iron slinkies), and a museum of oddities. Many of the exhibits and installations are made of recycled materials. I know of more than a few meeting attendees who snuck off during the meeting for a return visit!

On Friday, the SSAR 50th Year Symposium "Herpetology in the Age of Genomics" was held. Organized by Jonathan Losos, this symposium included 12 presentations and considered genomics very broadly, i.e., genome sequences of focal taxa as well as large-scale investigations (Fig. 4). This was a sequel to the symposium chaired by David Wake at SSAR's 25th Anniversary entitled "Molecular and Genomic Evolution of Amphibians and Reptiles" in 1982.

The highlight of the social events for many of our members was the 50th Anniversary Banquet, Program, and Live Auction held on Friday evening. Personal invitations were issued to past officers, editors, and committee chairs, however the banquet was open to all SSAR members and over 100 individuals attended. Many of the early officers of the OHS were there (Fig. 5), as well as sixteen Presidents, including the very first and our current President (Fig. 6). President Roy McDiarmid served as Master of Ceremonies for the evening and welcomed us to the Banquet. Kraig Adler spoke about the history of the Society. He particularly noted the involvement of students from the very founding of the Society and of the importance of volunteerism for SSAR and similar societies.



Individuals who have served the Society in particularly notable ways were presented with awards at the Banquet by President McDiarmid (Fig. 7). Roy made the point, that while these individuals certainly deserve special notice, they are representative of the many, many individuals who have made SSAR what it is today. Those honored were John Wright who published the first paper in the first volume of the first issue of *Journal of*

Another New Book to Celebrate SSAR's 50th Anniversary

THE LIVES OF CAPTIVE REPTILES

by Hans-Günter Petzold

Translated by Lucian Heichler and Edited by James B. Murphy

This book, originally published in German, is **a recognized classic on the biology of captive reptiles** (and selected amphibians). In it, the author carefully summarizes an enormous body of information—both his own extensive experience at Tierpark Berlin and a vast literature—much of which has been little known outside the German-speaking world. He synthesizes studies from captive and wild animals and discusses and interprets them in terms of contemporary physiology, ethology, and reproductive biology. Petzold reviews papers in biological, herpetological, zoo, and terrarium journals published throughout the world, including eastern Europe, Russia, and China, and he champions the role played by amateur terrarists in making studies of general importance. He shows how data derived from captive reptiles can lead to discoveries of importance to ethology, reproductive biology, systematics, and veterinary management. **This book will be of value to academics, zoo personnel, veterinarians, amateur terrarists, and conservationists interested in the maintenance, reproduction, and observation of reptiles in captivity.**

Hans-Günter Petzold, late Curator of Reptiles and Deputy Director of the Tierpark Berlin, one of the world's great zoos, was a leading expert on the biology of captive amphibians and reptiles and author of about 350 papers and five books on captive animals. He was trained at the University of Leipzig in systematics, ecology, and animal behavior, where he received his doctorate in 1960, and has conducted field research on reptiles overseas, including Algeria, Cuba, and Vietnam. In this book, Petzold has marshalled this breadth of experience to make insightful connections among diverse studies and to point out fruitful areas for future research. This English edition has been professionally translated by **Lucian Heichler**, who for more than 30 years served in the foreign service of the U.S. Department of State, and has been thoroughly edited by **James B. Murphy**, former Curator of Reptiles at the Dallas Zoo and now Research Associate at the Smithsonian Institution's National Zoological Park in Washington, D.C. The German edition was not illustrated, but this edition has been augmented by the staff of Tierpark Berlin with **60 photographs (57 in color)**.

Topics covered include aspects of **reproduction** (sexual dimorphism, age at maturity, sex recognition and attraction, courtship behavior, copulation, gestation and delayed fertilization, egg-laying, birth, reproductive cycles, parental care, data on eggs and clutches, incubation time, genetic questions), **development** (growth, coloration and markings, regeneration, skin shedding, longevity), and **nutrition** (search for and ingestion of food, digestion, excretion, defecation, pellet formation, gastroliths, keratophagy, cannibalism). There are also discussions of the origin and **history of zoos**, the relevance of **terrarium observations**, and species **conservation programs** in zoos and private terraria. The literature cited section includes 1200 titles and there is an index to genera and species.

Specifications: 300 pages (7 × 10 inches or 18 × 25.5 cm), hard cover, 60 photos (57 color), index. ISBN 978–0–916984–73–1. To be published March 2008. • **Regular Price:** $55. • **Special Price to SSAR Members** (if ordered *before July 2008*): $45. • **Shipping Costs:** USA address, add $4; non-USA add $11. • **Orders to:** SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158–0517, USA (*telephone and fax*: 801–562–2660; *e-mail*: ssar@herplit.com). • **Payment:** Make checks payable to "SSAR." Non-USA orders must be paid in USA funds using a check drawn on a USA bank or by International Money Order. Books may be charged to American Express, Discover, MasterCard, or VISA (please give account number and expiration date). • **SSAR Membership and Other Publications:** Membership information and a complete list of society publications can be obtained from the Publications Secretary at the addresses given above or at www.ssarherps.org.

Herpetology ("Variation in Three Sympatric Sibling Species of Whiptail Lizards, Genus *Cnemidophorus*"), Bob Aldridge for his service as Publications Secretary and Treasurer, Joe Collins who has served the Society in many capacities (President, Secretary, Editor, etc.), Doug Taylor (Treasurer for 6 years and Publications Secretary for 10 years), Bob Powell (editor of *CAAR* for 13 years and who introduced color into the *Catalogue*), Corson Hirschfeld (long-time member, President, 1962–1965, and developer of *Herpetological Review*), Stephen Tilley (Publications Secretary and Editor of *CAAR*), and Robert Hansen (Editor of *Herpetological Review* since 1991). Special 50-year service awards were presented to the co-founders of the Society, Kraig Adler (President, Editor, member of various committees, etc.) and David Dennis (Secretary, Treasurer, and artist, etc.) (Fig. 8).

A slide show of the history of the Society and its members, organized by Al Savitzky and Roy McDiarmid, ran throughout the evening. Beautifully etched wine glasses with the SSAR logo designed and produced by Ronn Altig were given to attendees (all 125!) at the Banquet (Fig. 9). A few additional glasses were auctioned later in the evening and some lucky members walked away with a set of four. Joe Collins, who was the original SSAR auctioneer in 1981, agreed to return in the role of auctioneer for the 50th Anniversary Auction, assisted by Darrell Frost and Chuck Schaffer. As always, bidding was spirited and much needed funds were raised for Student Travel Awards.

On Saturday morning, in honor of the 300th Anniversary of the birth of Carolus Linnaeus, the International Society for the History and Bibliography of Herpetology and HL sponsored a symposium "The Historical Legacy of Linnaeus: A Celebration of the Linnaean Tercentenary."

The Joint Meeting Picnic was held in the St Louis Zoo in the hills of Forest Park on Saturday evening. Established in 1910, state legislation provided that admission to "the zoo shall be forever free." We enjoyed local barbeque and having free rein around the zoo. Many herpetologists spent time in the historic Charles H. Hoessle Herpetarium (renamed in 2002 in honor of the Zoo's Emeritus Director) that was built in 1927 as "The Reptile House" and currently houses over 700 animals, including live tuatara. This is the collection made famous by TV personality and zoo director, Marlin Perkins.

To celebrate this special year for SSAR, all meeting attendees received a copy of a poster produced by David Dennis of an Ohio *Hyla versicolor* (Fig. 10). Also on display were posters produced by Dave for the 1982 and 1989 meetings at North Carolina State Museum of Natural History, Raleigh, North Carolina and the University of Kent, Canterbury, United Kingdom, respectively (Fig. 11). The 1982 meeting occurred during our Silver Anniversary year and the 1989 meeting was held in conjunction with the First World Congress of Herpetology.

Throughout the meeting, Breck Bartholomew (Publications Secretary) displayed a remarkable collection of SSAR publications (Fig. 12). Breck began collecting all SSAR publications as well as originals for works reprinted and translated by SSAR after attending the 1996 meeting and seeing the display at the Spencer Library at the University of Kansas (this display was converted into "Slithy Toves"—an SSAR book). The display at the 50th meeting included originals of approximately 80% of the books reprinted by SSAR and all of the original versions of the books translated and published in English by SSAR. Many of the books are quite rare (some valued at more than $40,000), are highly sought after, and are seldom seen in herpetological collections. Breck expressed a hope that the display would act as a tribute to the Society and highlight the importance of the publications in the history of SSAR. In the same room was a display of all of OHS and SSAR's prior publications (selections of journals) and other historical documents, as well as a display of some of Linnaeus' publications in celebration of his tercentenary, arranged by Richard Wahlgren (Fig. 13).

The Herp Quiz was revived at this meeting thanks largely to the efforts of Marty Crump, Julian Lee, and John Simmons. As always, this quiz contained questions to stump even the most knowledgeable herpetologist! Winners were announced at the Joint Meeting Banquet at the end of the meeting. Winners of the student category were Eric Rittmeyer and Michael Grundler (both undergraduates from Cornell) and of the non-student category were Robert Reed and Bjorn Lardner.

The Joint Meeting Banquet was held on the last evening of the meeting. Larry Page (Past President ASIH) served as Master of Ceremonies and in his opening remarks acknowledged the 50th Anniversary of our Society (Fig. 14). ASIH made various awards including the Robert K. Johnson Award to our own Al Savitzky recognizing his long service to ASIH. Resolutions of the Societies were presented by Joe Nelson and Rafe Brown (for SSAR). David Green issued an invitation to attend the 2008 Joint Meeting of Ichthyologists and Herpetologists in Montreal.

Once again, SSAR extends thanks to the local co-hosts, other members of the Local Committee (especially the graduate students), and Sharon Brookshire and the staff of the Kansas State University Division of Continuing Education for all of their hard work, particularly as regards special events commemorating our Anniversary.

Board Meeting and Business Meeting Summaries

Society President Roy McDiarmid called the 2007 Board Meeting to order at 0802 h July 11th at the Hyatt Regency Hotel, St Louis, Missouri.

In attendance were 10 members of the Board of Directors and 17 Editors, Committee Chairs, or members of the Society. Minutes of the 2006 Board of Directors Meeting (New Orleans, Louisiana) were approved.

Annual reports for 2006/2007 were submitted by 31 of 32 Officers, Editors, and Committee Chairs. President Roy McDiarmid devoted much time in the first six months of his term to preparation for the celebration of SSAR's 50th Anniversary. For example, letters of invitation, particularly to attend the 50th Anniversary Banquet, were sent to all current and past officers of the Society and editors of SSAR publications. Awards and plaques recognizing certain individuals who have served the Society in special ways were arranged. Other routine duties that occupied Roy included those related to the Metter Award and the Symposium, Conservation, and Standard English and Scientific Names Committees. He was involved in the transition of the Treasurer's duties from Dora Pinou to Kirsten Nicholson and in moving the membership responsibilities to Allen Press. The Herpetologists' League is also working with Allen Press and this joint arrangement will result in financial savings for both societies. Roy invites feedback from members regarding interactions with Allen Press. He spoke with the Allen Press representatives at the meeting about some issues that had already been raised. John Moriarty pointed out that there are some issues relating to the Allen Press website that need to be resolved, e.g., there are no links to SSAR publications with which Allen Press is not involved, it is not currently possible to separately access lists of HL and SSAR members on the website, etc. President McDiarmid and George Pisani (Archivist) are working with the Smithsonian Archives which is willing to review a proposal to accept SSAR materials. A committee will be appointed to deal with this. Those interested in being appointed to this committee should contact Roy.

During the last six months of her term as President, Robin Andrews (Immediate Past-President) finalized the agreement between SSAR and HL and Allen Marketing and Management (AM&M, effective April 2007). AM&M will now handle subscription and membership services and the society will be able to broadcast email information to members. Robin appointed Betsy Rothermel as co-chair of the Conservation Committee and wrote letters of thanks to the members of the Local Committee who organized the very successful 2006 Annual Meeting in New Orleans. Additionally, she worked with Gad Perry and Geoff Smith to write an ethics statement for SSAR (this is posted on our webpage) and with Zack Walker to update the webpage. She was also involved in planning for the 50th Anniversary Celebration.

Kirsten Nicholson (Treasurer) reported that assuming the duties of the Treasurer's office continued to be challenging, but she is successfully handing the day-to-day responsibilities of the position. She plans to write a manual outlining the duties of the Treasurer. This will ease the transi-

tion to a new Treasurer when this occurs. Kirsten suggested that the Board should discuss endowments and investments. She has changed the way that page charges are invoiced. Authors will now be emailed a PDF copy of the first page of galley proofs. There was discussion of annual repayments of a loan to a Venezuelan foundation for the SSAR book, "Turtles of Venezuela."

Among her duties in the past year, Marion Preest (Secretary) prepared Board and Business meeting minutes for officers, editors, and committee chairs. Additionally, she prepared a summary of the 2006 meeting for publication in *Herpetological Review* and prepared the Annual Report for this year's Board meeting. On-going duties include updating SSAR letterhead, answering or forwarding numerous emails, and ensuring that reports from Committee chairs are submitted for publication.

Breck Bartholomew (Publications Secretary) reported that total income from sales of Society publications in 2006 was $184,031 (this includes $159,912 in membership dues). Book sales appear to have slowed a little in 2006. Breck suggested that this was due to people not purchasing as many books as they used to and the fact that the Society has not published many books recently. He expects sales to pick up next year particularly with the appearance of multiple volumes in the *Biology of the Reptilia* series. Breck was heavily involved in moving the membership duties to Allen Press.

Andy Price (Editor, *Catalogue of American Amphibians and Reptiles*) reported that 20 accounts were published in 2006. He wished to thank Larry David Wilson who stepped down as Snake Section Editor after serving for 34 yrs and Bob Powell for his service as Editor. Breck Bartholomew has started scanning old copies of *CAAR* (saving them as PDF's). Aaron Bauer suggested that access to this material (on a CD) could be used as an incentive to new members. Al Savitzky raised the issue of selling these files to provide income to the Society versus making them available free (via Open Access) and providing a service to professional herpetologists. Barbara Savitzky pointed out that electronic versions of literature have much greater appeal to younger members than to most of our older members.

No books in the *Contributions to Herpetology* series were published in 2006, however Kraig Adler (Editor) anticipates four in 2007–2008, including two volumes in the *Biology of the Reptilia* series. *Contributions to the History of Herpetology* (Vol. 2) by Adler, Applegarth, and Altig was distributed *gratis* to all delegates at the 2007 meeting, and includes biographies of almost 300 leading herpetologists, an index to taxonomic authors, and an update of doctoral lineages (Fig. 15). Three books are expected in 2008, including two in the *Biology of the Reptilia* series. Volume 22 will be the last in the series and will consist of a comprehensive index.

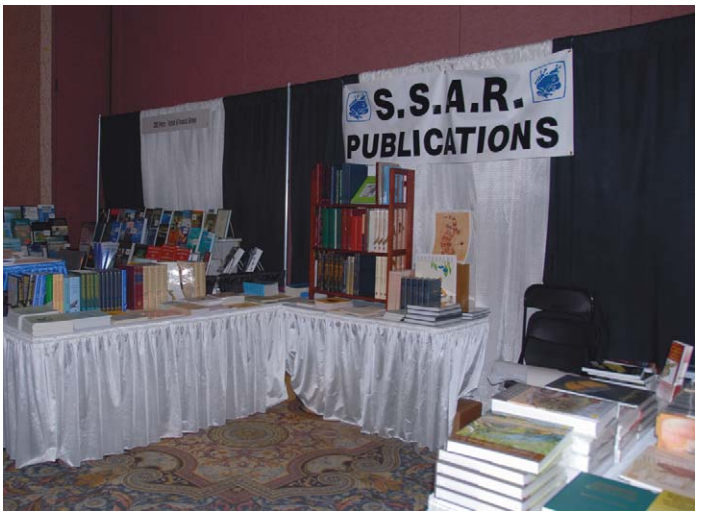
Editor of *Facsimile Reprints in Herpetology*, Aaron Bauer, reported that one facsimile was published in early 2007 (*The Herpetological Contributions of Mario Giancinto Peracca*) and two are planned for 2008 (*Gray's Catalogues of the Specimens of Amphibians and Reptiles in the Collection of the British Museum*, and a special World Congress of Herpetology facsimile for distribution in Brazil, Schweigger's papers on turtles). Several other works are in preparation or under consideration. For the foreseeable future, one *Facsimile* is likely to be published every two years.

John Moriarty (Editor) reported that *Herpetological Circulars* Numbers 35 and 36 have been published this year. Number 35 will be printed on demand and Number 36 *(Society for the Study of Amphibians and Reptiles: A Fifty Year History*) was distributed at the 2007 Annual Meeting (Fig. 16). Number 37 (*Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, Sixth Edition*, by Crother et al.) is scheduled for early 2008 and will likely have an accompanying website link.

Volume 2 of *Herpetological Conservation* (Conservation of Reptiles in Canada, edited by P. S. Corn) was published in May 2007. The Board wishes to acknowledge Breck Bartholomew for his assistance. Joe Mitchell (Co-Editor, *Herpetological Conservation*) reported that Volume 3 (Urban Herpetology) is nearing completion and publication is expected in 2008. This book will consist of over 40 chapters and a number of case studies and was partially funded by the U.S. Forest Service. Joe is interested in suggestions for a fourth volume in this series.

Robert Hansen (Editor) reported that *Herpetological Review* continues to increase in size but that submission rates seem to have leveled off. More space has been devoted recently to natural history notes to deal with a backlog of accepted manuscripts. There were minimal staff changes in 2006–2007. There was consideration of increasing the use of color in *Herpetological Review* and Bob plans to discuss this with Allen Press. Al Savitzky commented that *Herpetological Review* is the only major North American journal that is not yet available online. The Board realizes the importance of online availability and will continue discussion of this. Hard copies in black-and-white plus online publication in color may be possible. The Board once again thanked Bob for his impressive efforts with this news-journal.

Geoff Smith (Editor, *Journal of Herpetology*) reported a number of staff changes in the past year (four new Associate Editors and one addition to the Editorial Board). Allen Press now provides copy editing services. Geoff expects submissions this year for the first time to exceed 300 (perhaps partly because of ease of online submission). Acceptance rate remains approximately the same as it has been the past few years (i.e. ~ 40%). As a result of these factors, a backlog of accepted papers is being generated. An increase in number of pages is planned to relieve this pressure. Many manuscripts are received from overseas herpetologists, and many of this year's papers are from students eligible for the Kennedy Award. An ethics statement was developed by Geoff with assistance from Gad Perry and Robin Andrews. This statement is considered "a work in progress" and comments on it are welcome (contact Geoff Smith). The 50th Anniversary of SSAR is being commemorated with golden covers for *Journal of Herpetology* as well as cover art depicting the 1st meeting of SSAR and color photos of new species described in the *Journal*. Geoff expressed thanks to Kraig Adler and Al Savitzky particularly for help with this. There was some discussion of the editorial policy of *Journal of Herpetology* regarding the suitability of manuscripts based on descriptive research. Geoff indicated that these types of manuscripts will be considered for publication if the biological context within which they are presented is appropriate. The Board reiterated its support for all aspects of quality herpetology. Color plates are thought to be valuable in *Journal of Herpetology* especially in descriptions of new species. It may be possible to use endowments to support this or to publish color plates online and use black and white in the hard copies.



Reports submitted by the Chairs of Standing Committees were then discussed. The Committee on Celebration of the 50th Anniversary of SSAR (Al Savitzky, Chair) reported that it had been active planning a number of major events for the Annual Meeting including a commemorative banquet preceding the live auction, a symposium "Herpetology in the Age of Genomics," and reviving the Herp Quiz. The Board decided that entry to the Quiz would be by donation and that funds raised would be used to support the Student Travel Fund. All registrants at the Annual Meeting received a photographic poster produced by David Dennis, a copy of *Contributions to the History of Herpetology* (Volume 2) edited by Kraig Adler, and *Society for the Study of Amphibians and Reptiles A Fifty Year History, 1958 to 2007* by John Moriarty and Breck Bartholomew. A comment was made that the Board should pay attention to the timing of major events in the history of other Herpetological Societies so that letters of recognition may be sent to them. The Secretary will see to this.

Stephen Richter and Betsy Rothermel, co-chairs of Conservation Committee attended the annual Southeast Partners in Amphibian and Reptile Conservation (PARC) meeting and discussed with PARC members how activities of SSAR, HL, ASIH, and PARC might be better coordinated. The Committee sent a letter to the US House Committee on Science regarding the decision by the Department of Energy to suspend funding for the Savannah River Ecology Lab. Following this, there was some discussion of the autonomy of this and other SSAR committees, and whether a

letter written by members of a Committee representing SSAR should be signed by the President since Roy McDiarmid is a federal employee. Robin Andrews did not think that SSAR has a policy regarding this and suggests that whether or not the President signs such a letter should depend on the importance of the issue being discussed. Roy McDiarmid commented that government employees needed to be careful what they sign their names to and suggested that even if the President does not sign letters, he/she should be aware of their content. The Conservation Committee is planning to meet with the ASIH Conservation Committee and the SSAR/HL Herp Education Committee during the Annual Meeting.

Nine proposals of high quality were submitted for the Dean Metter Award (Joe Beatty, Chair) this year. The Award was presented to Barbara Banbury for her proposal "Tempo and Mode of Species Diversification in Megophryid Frogs." Ms. Banbury has worked with Drs. Linda Trueb, John Simmons, Robert Powell, and Anne Maglia and is currently a Ph.D. student in the lab of Dr. Michael Alfaro at Washington State University.

Erik Wild (Chair, Grants in Herpetology Committee) reported that 71 proposals from 26 states in the USA and eight countries were received in 2007. The "Travel" and "Laboratory" categories received the most applications (21 each). The following winners will each receive $500:

Conservation: Dana Wingfield, University of California, Santa Cruz
Field Research: Julie Ray, Old Dominion University
Laboratory Research: Michael Butler, University of Florida
Travel: Roberto Brenes, Southern Illinois University
International: Hanyeh Ghaffari, Azad University, Tehran (Iran)
Education: Justin Shaw, National Audubon Society

Erik is stepping down as chair of this committee and will be replaced by Josh Kapfer. In the future, applications for GIH will be submitted online. Josh will work with Zack Walker and Anne Maglia to implement this.

Lora Smith and Margaret Gunzberger (co-chairs) announced the winners of the 15th annual Henri Seibert Award at the meeting in New Orleans, 2007. Names of the winners were published in *Herpetological Review* 37(3):257–258. SSAR wishes to thank Chuck Crumly (University of California Press) for, once again, providing books for the winners. There was some discussion of the requirement that participants be members of SSAR at the time of abstract submission. Every year a handful of students apply to participate in this competition without being members and it takes many emails and many weeks to deal with this. It is hoped that online membership renewal will eliminate this problem.

The Herpetological Education Committee (Cathy Bevier, Chair) continues to respond to "Herp Hotline" questions and plans to develop a "Frequently Asked Questions" page and a webpage listing educational activities on herpetofauna for all ages. Members of the committee are involved with informal education activities, e.g. interviews, open house presentation, field trips. In the past year, they have updated the International Grants Programs list on the SSAR website. The Board gave approval to replace two members of the committee and to include a representative from ASIH. Lynnette Sievert (Chair, Kennedy Student Award Committee) reported that the winning paper for 2006 was by John Malone: "Ecology of the Basin Construction Reproductive Mode in *Smilisca sordida* (Anura: Hylidae), *Journal of Herpetology* 40:230–239." John will receive a check for $200 or the equivalent of $400 in SSAR publications.

Henry Mushinsky (SSAR Representative on the Meeting Management and Planning Committee) reported that this Committee met in St. Louis in March to develop a meeting schedule and review conference facilities. They extended the deadline for abstract submission for the 2007 meeting because of undersubscription at the original deadline. Approximately 900 presentations will be made at the 2007 meeting. The Committee requests that Society members read the submission instructions carefully to avoid making mistakes. They provided a reminder that each person can submit abstracts for only one oral paper and one poster.

Future meetings are to be held as follows:

– Montreal, Canada (2008, 23–28 July)
– Portland, Oregon (2009)
– Providence, Rhode Island (2010)
– Minneapolis, Minnesota (2011)

The Board continued to discuss participation of SSAR in meetings of the World Congress of Herpetology (WCH). In principle, we would like to meet with WCH when the meeting is held in North America. However, problems arise over the advanced planning that is necessary. Aaron Bauer (WCH Secretary-General-elect) indicated that a decision regarding the 2012/2013 meeting should be made by the end of this year. The venue is likely to be Tucson, AZ or Vancouver, BC. There was unanimous support expressed by the Board for SSAR to meet with WCH in 2012 in North America. Our level of involvement would need to be specified. There is nothing in the SSAR constitution that would prevent SSAR from having a presence at more than one meeting per year, thus it might be possible to participate in both the WCH and Joint ASIH/HL/SSAR meetings. The Board agreed to co-sponsor the 2008 WCH meeting in Manaus, Brazil. There was on-going discussion of the current hotel-based meetings with professional organizers versus the former university-based meetings and the issues of cost, ease of planning, and workload placed on the local hosts.

No election is scheduled for 2007. Greg Watkins-Colwell has been added to the Nominations Committee (Kirsten Nicholson, Chair) and an overseas member is being sought. Richard Wassersug (Resolutions Chair) presented resolutions at the Joint Meeting Banquet in 2006 and Rafe Brown presented them (for Richard) in 2007. Kraig Adler suggested that SSAR abandon the use of antiquated language in the resolutions. There was general support for this.

Brian Crother (Chair, Standard English and Scientific Names Committee) reported that Number 37 of *Herpetological Circulars* (*"Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico,"* by Crother et al.) is planned for 2008 and will likely have an accompanying website link. There was some discussion of the importance of this list and the fact that it has official approval of SSAR, HL, and ASIH. Brian currently receives many requests (e.g., by State agencies) for the list produced by this committee and the Board regards this as a worthwhile investment. There was also discussion of the need for both electronic and hard copies of publications. Some concern was expressed regarding citation of non-static, electronic-only documents. Roy McDiarmid suggested that Brian and John Moriarty talk with Anne Maglia or Zack Walker (Web Oversight Committee) about this. The committee has received a draft of "*Standard Spanish, English, and Scientific Names of the Amphibians and Reptiles of Mexico*" by Ernest Liner and Gustavo Casas-Andreu and recommends publication in limited paper run and as a downloadable pdf from the SSAR website. This manuscript will be sent out for review. The importance of including Spanish-speaking Mexican colleagues in the pool of reviewers was stressed. John Moriarty thinks that he will be able to find a donor to cover publication costs. The Board discussed the possibility of Brian Crother stepping aside from his position as chair of this committee now that he is President-Elect. However, the Board sees no conflict of interest and wishes for Brian to remain in this position.

Dawn Wilson reported that the number of applicants for Student Travel Awards continues to be low (12 applications for 10 awards). The Travel Award Winners in 2006 were:

Kimberly Andrews, University of Georgia (USA)
Kristin Bakkegard, Utah State University (USA)
Alessandro Catenazzi, Florida International University (USA)
Matt Chatfield, University of Michigan (USA)
Chris Feldman, Utah State University (USA)
Gillian Gouchie, Dalhousie University (Canada)
Joshua Kapfer, University of Wisconsin (USA)
Libby Liggins, Victoria University of Wellington (New Zealand)
Carolina Monteiro, University of Arkansas (USA)
Heather Waye, Oregon State University (USA)

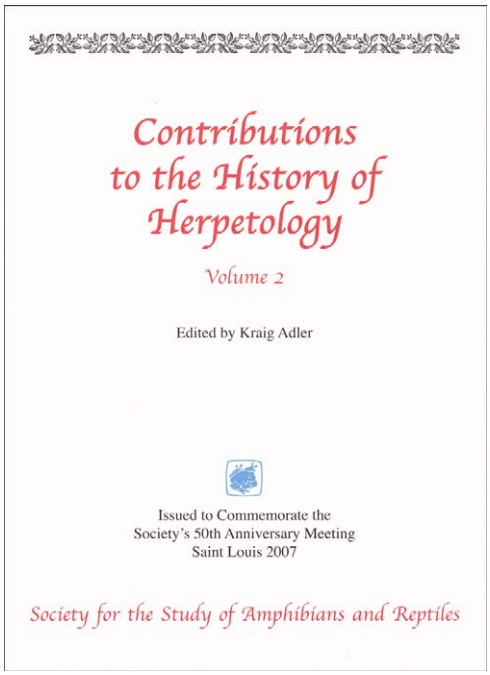

FIG. 15. Title page of "Contributions to the History of Herpetology," Vol. 2 issued to commemorate the 50th Anniversary of the Society. This volume contains "Herpetologists of the Past," Part 2 by K. Adler, "Index of Authors in Taxonomic Herpetology," 2nd ed. by J.S. Applegarth, and "Academic Lineages of Doctoral Degrees in Herpetology," 2nd ed. by R. Altig.

Anne Maglia (Chair, Web Oversight Committee) reported that the website underwent a major update this year. A number of individuals, including Committee members, assisted with this. A link to the website of Allen Marketing and Management (AM&M) will be provided from the Society website. Anne indicated that if the Society starts to publish more material on the website (e.g., PDF files) there will be an increase in costs. The website is very important in maintaining visibility for the So-

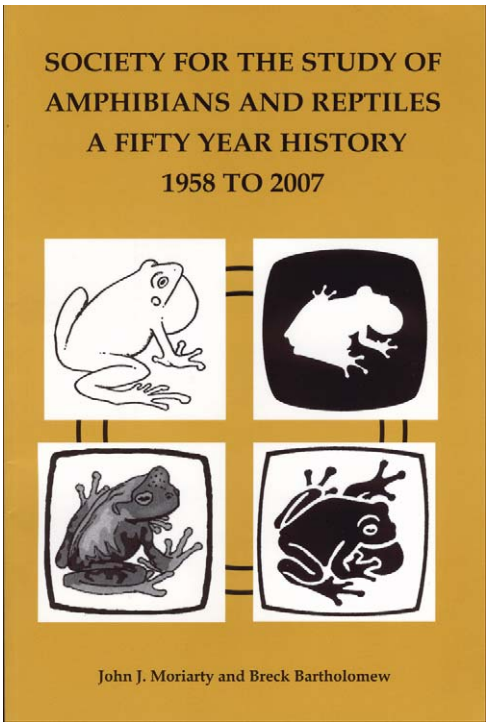

FIG. 16. Cover of "Society for the Study of Amphibians and Reptiles A Fifty Year History 1958 to 2007" by J. J. Moriarty and B. Bartholomew.

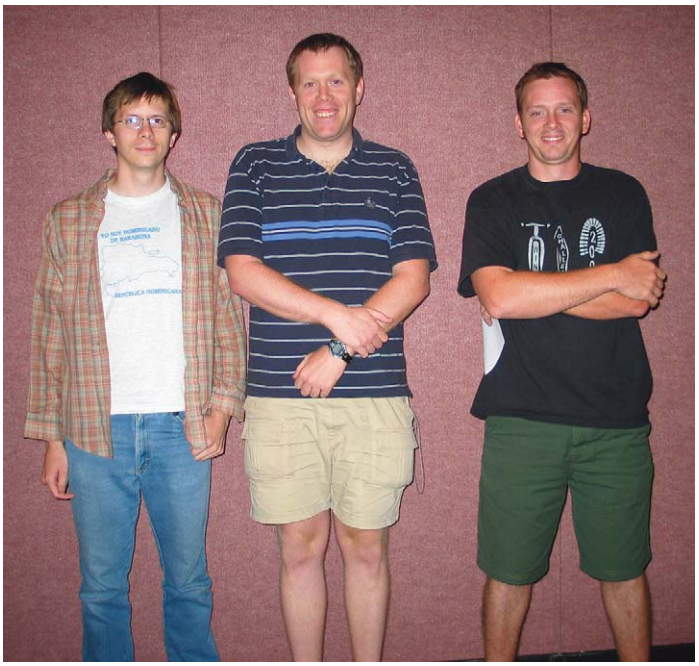

FIG. 17. Three winners of the 2007 Henri Seibert Awards for best student papers who were in attendance at the SSAR Business Meeting. From left to right: L. Mahler (Systematics Category), R. Sutherland (Conservation Category), and S. Graham (Physiology/Morphology Category). Photo by M. Preest.

ciety and the committee welcomes suggestions from members.

The SSAR election for 2007 was conducted during the Fall of 2006. Maureen Kearney (Elector) received 278 ballots. Brian Crother was elected President-Elect, Kirsten Nicholson was elected Treasurer, and Marion Preest continues as Secretary. Tiffany Doan, Travis LaDuc (Regional Society Representative), Stephen Richter (Conservation Representative), and Paul Chippendale were elected to the Board. No election is necessary in 2007, and from 2008 forward, elections will be run electronically. It is hoped that this will avoid the problem of overseas members not receiving ballots on time and may increase voting participation. Members who do not have access to email will continue to receive paper ballots. Maureen Kearney has resigned as Elector after several years of excellent service. There was discussion of the need to have an Elector, given the move to electronic voting and the fact that AM&M will be counting votes. It was felt necessary to have an election overseer and that perhaps this person could be an international member of the Society. Among other duties, the overseer could deal with the issue of family membership categories and ensure that couples/families with these memberships are able to cast the appropriate number of votes.

Al Savitzky (Representative to AIBS and BioOne) attended the annual meetings of both AIBS and BioOne in 2007 and reported on their activities as relevant to SSAR. AIBS continues to serve as an important voice for organismal biologists and ecologists. It deals, among other things, with public policy and biological education at all levels (focusing particularly on the controversies surrounding the teaching of evolution) and is currently involved in the cooperative development of a proposal to begin study of the current state of biological sciences in the U.S. Concern was expressed at the AIBS meeting at declining membership in many member societies due to a failure to recruit or retain young professionals. Information was presented on the recently launched Encyclopedia of Life. This will link many biological databases and provide information on biodiversity for use by professionals and the public.

A major new project is the *Coalition for the Public Understanding of Science* (COPUS). The first major activity of COPUS is to organize the "Year of Science 2009." This year is the bicentennial of the birth of Darwin, the sesquicentennial of the publication of *The Origin of Species*, and the bicentennial of the birth of Abraham Lincoln (who founded the U.S. National Academy of Sciences). The aim of the celebration is to focus on public understanding of the process of science. The Board voted unanimously to join COPUS and the Year of Science 2009. Information on COPUS can be found at http://www.copusproject.org and on the Year of Science 2009 at http://www.yearofscience2009.org.

BioOne launched a second collection of journals in 2007 under the name BioOne.2. Between BioOne.1 and BioOne.2, 125 journals are available (this is expected to grow to almost 170). BioOne has instituted a 52% increase in price over the past 6 yrs, but has offset this by an 88% increase in the number of titles and a 323% increase in the number of pages. Savitzky reported that BioOne continues to be supported by libraries. BioOne has returned 61% of its total 2006 revenue to publishers (SSAR received $15,235 in 2006 for 2005). SSAR is not currently enrolled in BioOne's Secondary Rights Management Program. This provides opportunities for journals to receive income from the sale of individual articles.

One proposal "Is Management of Sustainable Commercial Harvesting of Long-Lived Organisms Possible?" was received from Willem Roosenburg by Richard Durtsche (Symposium Coordinator) for the 2008 Montreal meeting. This Board voted in February to support this symposium. Individuals considering submitting proposals for 2009 need to ensure that they are aware of the new guidelines.

Following discussion of the Annual Reports, the Board moved on to new business. There was discussion of mounting another membership campaign. Membership numbers clearly increase following a campaign and such campaigns appear to be especially important in recruiting overseas members. Now that dues can be paid online, it may be easier to recruit overseas members. We particularly need to recruit (and retain) younger members. A suggestion was made to send membership brochures advertising the benefits of joining SSAR to other societies and to their meetings (e.g., WCH meeting in Manaus in 2008). Breck Bartholomew and John Moriarty (with advice from Kraig Adler) will spearhead this effort. There was discussion of various incentives that we could offer to new members (e.g., reduced page charges, reduction in prices of SSAR publications, etc.). Some concern was expressed that current/renewing members would not have these incentives available to them. Regional Herpetological Societies could also be targeted as sources of new members. Dave Hardy offered to work with Travis LaDuc on this. The Relations with Herpetologists at Zoological Parks Committee should also be involved.

The Student Travel Award is supported partly by proceeds from the Silent Auction. Dawn Wilson (Silent Auction organizer) reported that she has not been receiving the necessary support from local hosts and students (to obtain auction items and to run the auction) and the funds generated in recent years have been low. Dawn indicated her desire to step down as organizer. The Board then discussed the need for increased student involvement in the Society and various ideas to raise funds for student support. Student attendance at meetings is substantial and continues to increase. The cost to attend meetings is considered to be reasonable - housing costs can be on the low side with shared rooms and registration costs and cost of tickets to attend events are heavily subsidized by regular members. There was a suggestion to form a "Student Participation Committee" to determine why there is a general lack of participation by students in the Society and to generate ideas to increase involvement and student support. Dawn offered to chair this Committee and Rafe Brown, Tiffany Doan, Anne Maglia, and Stephen Richter indicated a willingness to become members. Others wishing to be involved (especially students) should contact Dawn or Roy.

A request for co-sponsorship of a symposium on "Amphibian Declines and Chytridiomycosis" was sent to the Conservation Committee by Joe Mendelson on behalf of PARC (Partners in Amphibian and Reptile Conservation). This symposium was held in Tempe, AZ in November 2007. The Board considered this a worthwhile symposium and voted unanimously to support it by providing $500. However, some concern was expressed that the money could be used to support other Society activities (e.g., student travel) and that, once it became known that the Society provides financial support, we would begin to receive multiple such requests.

The Board Meeting adjourned at 1345 h without having finished discussion of, or voted on, the 2008 Budget. As a result, a special Budget meeting was called.

Society President Roy McDiarmid called the Budget Meeting to order at 1530 h on July 12, 2007 in the Hyatt Regency, St Louis, MO. Treasurer Kirsten Nicholson presented a proposed 2008 budget. As first proposed, expenses exceeded income by approximately $60K. The Board then reviewed income and expenditure categories. Expenditures were cut in some cases where this was deemed possible. This had relatively little impact on the proposed budget. Income for 2008 from publications is expected to be higher than currently listed in the budget especially because of books from the *Contributions* series that will appear. This may add $20–40K to our income, however there is still likely to be a deficit.

There was discussion of raising the annual dues. The Board felt that a dues increase may be necessary especially given that dues have not increased since 2003, our current dues are lower than those of the other major USA-based societies, and we give "value for money" e.g., two journals with four issues each year, various forms of student support (travel awards, Kennedy Award, Seibert Awards, Grants-in-Herpetology, Dean Metter Award, etc.). However, it was decided to put this matter off temporarily, partly because of the recent change in Treasurer. It was agreed that an in-depth analysis of the financial state of the Society was necessary. After that, the implications of a dues increase could be looked at and

the size of that increase could be determined. The Board will revisit this issue at the 2008 Board Meeting. In the meantime, we realize that if there is a budget shortfall, we will need to dip into our investments.

The proposed 2008 budget was approved and received unanimous support.

Income estimated at $243,368
Expenses estimated at $296,560
(Deficit = $53,192)

The budget meeting adjourned at 1915 h.

The Annual SSAR Business Meeting was called to order by President McDiarmid at 1604 h on July 14th. Approximately 47 SSAR members were in attendance. David Green issued an invitation to attend the 2008 Annual Meeting in Montreal, Canada and Dick Vogt issued an invitation to attend the 6th World Congress of Herpetology in Manaus in 2008. President McDiarmid then summarized the meeting of the Board of Directors held a few days earlier. Larry David Wilson, long time Snake Section Editor (*CAAR*), received applause for his 34 years of service to SSAR in this capacity. Winners of the 2006 Dean Metter Award, Kennedy Award, Henri Seibert Student Awards (Fig. 17), Grants-in-Herpetology Awards, and Student Travel Awards were announced.

There was discussion of the costs of attending recent Annual Meetings. For some members (e.g., retirees) these costs are prohibitive. There was a suggestion that we add a small amount (e.g., $5) to the registration fee and the money raised could go into a pool to support members who otherwise would not be able to attend. Improving the ability to find compatible roommates and implementing an online "rideshare" program could make attendance at meetings possible for more of our members.

Discussion then turned to making the Annual Meeting more "student-friendly" and making it easier for students to learn who does what in SSAR. A suggestion was made that Officers and Editors present their own reports at the Business Meeting rather than the President as was done in years past. The scheduling of the Board Meeting (which begins in the morning of the day most attendees arrive) makes it difficult for students (and others) to attend (even though the Board Meeting is open to all SSAR members) because it would require them to arrive at the meeting venue a day earlier. It was suggested that the Board Meeting be rescheduled to occur later in the meeting; however, this would interfere with other scheduled activities and the ability of Board members to attend talks and poster sessions. There was discussion of a mentoring program and of arranging a reception specifically for student members of SSAR to welcome them to the meeting and enable them to get to know Board Members, Editors, and Committee Chairs. This reception could feature particularly prominent herpetologists who would introduce themselves to students. President McDiarmid promised a Welcome Reception for the 2008 meeting. Several students expressed interest in joining the Student Participation Committee.

The meeting was adjourned at 1745 h.

—Respectfully submitted by Marion Preest, SSAR Secretary

I would like to acknowledge the assistance in writing this report and photographs that I received from the following individuals: Kraig Adler, Breck Bartholomew, Dave Dennis, Ken Dodd, Bob Hansen, and Joe Mitchell.

Kennedy Student Award

The Kennedy Award Committee (Carl Anthony, Bill Lutterschmidt, Terry Schwaner, Wayne VanDevender, Lynnette Sievert, Chair) has completed its work for Volume 40 of the Journal of Herpetology. The Committee has selected "Ecology of the Basin Construction Reproductive Mode in *Smilisca sordida* (Anura: Hylidae)" by John H. Malone (Vol. 40:230–239). The Kennedy Award carries with it a cash prize of US $200 or the winner's selection of any SSAR publications valued at twice that amount.

The committee invites all student members of the Society to submit their work to the Journal, and encourages regular members who supervise the work of students to draw this award to the attention of those students.

Dean Metter Memorial Award

There were nine proposals submitted this year for the Dean E. Metter Memorial Award. Since the proposals were all of high quality, the committee required more time to deliberate than in previous years, and the decision was more difficult. The committee has unanimously selected Barbara Banbury to be the fifth recipient of the Metter Award. Ms. Banbury's proposal was entitled: Tempo and Mode of Species Diversification in Megophryid Frogs. Anne Maglia recused herself from the decision making process this year because Banbury did her master's degree under her supervision.

Barb Banbury graduated with a B.S. in Organismal Biology from The University of Kansas where she worked under the supervision of Dr. Linda Trueb and John Simmons, the Herpetology Collection Manager. She also was a participant in Dr. Robert Powell's NSF sponsored REU Program at Avila University. Her Master's degree was completed at the University of Missouri—Rolla where she explored the development of cranial and post-cranial elements in pelobatid tadpoles in Dr. Anne Maglia's laboratory. In 2006, she began her PhD work with Dr. Michael Alfaro at Washington State University.

Applications for the 2008 Metter award are due no later than 29 February 2008 and in order to be eligible, applicants must be members of SSAR with dues paid by 31 December 2007. The winner of the award for 2008 will be announced around 1 April 2008. Please see the SSAR web page for details on how to prepare an application. Applications should be submitted electronically to Joe Beatty (e-mail: beattyj@science.oregonstate.edu).

Annual Report (2007)
Grants-in-Herpetology Committee

An award in the amount of $500 was made to each of the following individuals:

Conservation.—**Dana K. Wingfield**, University of California Santa Cruz. Project title: "Elucidating the oceanographic processes that affect the endangered juvenile loggerhead sea turtle (*Caretta*

caretta) off Baja California Sur, Mexico."

Field Research.—**Julie M. Ray**, Old Dominion University. Project title: "Three dimensional study of a mid-elevation neotropical snake community."

Laboratory Research.—**J. Michael Butler**, University of Florida. Project title: "A genetic investigation into the population status and range intergradation of an endemic emydid subspecies, the Gulf Coast box turtle (*Terrapene carolina major*)."

Travel.—**Roberto Brenes**, Southern Illinois University. Project title: "Instantaneous growth rate and assimilation rates of Neotropical montane tadpoles."

International.—**Hanyeh Ghaffari**, Azad University, Tehran. Project title: "Ecology of the Mesopotamian soft shell turtle (*Rafetus euphraticus*) with implications for conservation and management in Iran."

Education.—**Justin J. Shew**, Starr Ranch Sanctuary, National Audubon Society, Trabuco Canyon, CA . Project title: "Snake Research: Educational Field Ecology Program at Starr Ranch Sanctuary (Trabuco Canyon, CA)."

2007 Grants-in-Herpetology Committee.—Chair: Erik R. Wild. Reviewers: Jeffrey Parmelee, Rafe Brown, Eli Greenbaum, Chris Parkinson, and Josh Kapfer. SSAR congratulates the 2007 GIH recipients and thanks the committee members for their efforts.

Grants-in-Herpetology 2008 Proposals

Proposals are now being accepted for the 2008 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Application deadline is 28 February 2008. Grant application details are available at:

<http://www.ssarherps.org/pages/GIH.html>

Seibert Award Winners for 2007

The sixteenth annual Seibert Awards were presented at the 50th Annual Meeting of the SSAR in St. Louis, Missouri July 12–17, 2007. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR, serving as an officer for over 20 years. In recognition of outstanding student presentations at the annual meeting, a single award is given in each of four categories: Morphology & Physiology (4 presentations), Evolution & Systematics (11 presentations), Ecology (16 presentations), and Conservation (12 presentations). All winners will receive a check for US $200 from SSAR and a book from University of California Press compliments of Chuck Crumly.

The Seibert Award Winners for 2007 were: **Morphology & Physiology**: Sean Graham (co-authors Ryan Early and Matthew Grober), Georgia State University, "Plasma corticosterone variation in free-ranging male cottonmouths (*Agkistrodon piscivorus*): diel, seasonal, and captive handling effects, and interactions with plasma testosterone." **Evolution & Systematics**: D. Luke Mahler, Harvard University, "Does ecology influence rates of phenotypic variation in island anoles?" Honorable Mention: Matthew Gifford (co-author Allan Larson), Washington University, "A multi-locus assessment of the phylogeography of *Ameiva chrysolaema* from Hispaniola. Honorable Mention: Michael Westphal, Oregon State University, "What can garter snakes tell us about coral snake mimicry?" **Ecology**: Amanda Subalusky (co-authors Lora L. Smith and Lee Fitzgerald), Texas A&M University, "Ontogenetic shifts in habitat use in the American alligator: another case for the importance of seasonal wetlands". Honorable Mention: Mizuki Takahashi (co-author Matthew Parris), University of Memphis, "A test of reproductive isolation between the subspecies of *Notophthalmus viridescens*." Honorable Mention: Shannon K. Hoss (co-authors Lora L. Smith, Gordon Schuett, Craig Guyer), Auburn University, "Home range and multi-scale habitat associations of the eastern diamondbacked rattlesnake (*Crotalus adamanteus*) in southwest Georgia. **Conservation:** Ronald Sutherland, Duke University, "Presence only models for rare North Carolina snake species confirmed with unbiased road-cruising data."

The judges for 2007 were Patrick Owen (Ohio State University, Lima, OH), Robert Reed (USGS, Ft. Collins, CO), Kevin G. Smith (Washington State University in St. Louis), Robert Espinoza (California State University, Northridge), Chris Austin (Louisiana State University), Frank Burbrink (College of Staten Island/CUNY), Mike Adams (USGS, Corvallis, OR), Michael Dreslik (University of Illinois Urbana-Champaign), James Vonesh (Virginia Commonwealth University), Brad Shaffer (University of California at Davis), and Lora Smith (Jones Ecological Research Center, Newton, GA).

NEWSNOTES

Slowinski Award Announced for 2007

The Center for North American Herpetology is pleased to announce that the recipient of The Joseph B. Slowinski Award for Excellence in Snake Systematics for 2007 is Brice P. Noonan, of the Department of Integrative Biology, Brigham Young University, Provo, Utah.

On 12 September 2001, the world lost one of its premier biologists, a loss that went virtually unnoticed in the wake of the tragedy that befell the United States the previous day. Joseph Bruno Slowinski, the 39-year old curator of amphibians, turtles, reptiles, and crocodilians at the California Academy of Sciences in San Francisco, died in the jungles of Burma from the bite of a venomous snake. Joe was bitten on 11 September and, despite heroic efforts to save his life by expedition companions and colleagues, succumbed to the effects of the bite the next day. Eventually, the world took notice, and numerous media outlets across the nation and throughout the world chronicled Joe Slowinski's exemplary career, cut so tragically short.

A distinguished committee, comprised of Simon Creer (University of Wales, Bangor), Hussam Zaher (Muesu de Zoologia da Universidade de São Paulo, Brazil), and Christopher L. Parkinson (committee chair, University of Central Florida), have deemed the paper "Dispersal and vicariance: the complex evolutionary his-

tory of boid snakes)" as the most distinguished paper on snake systematics to appear worldwide during 2006. The paper was co-authored with Paul T. Chippindale, and was published in Volume 40 of *Molecular Phylogenetics and Evolution*.

As senior author of the paper, Dr. Noonan becomes the fifth recipient of The Slowinski Award, and will receive a check from The Center for North American Herpetology for US $500 along with a commemorative memento in recognition of his achievement.

New Varanid Organization and Journal

The International Varanid Interest Group is a volunteer-based organization established to advance varanid research, conservation, and husbandry, and to promote scientific literacy among varanid enthusiasts worldwide. Membership to the IVIG is free, and open to anyone with an interest in monitor lizards. The Group publishes a quarterly journal, BIAWAK, which is available online at http://varanidae.org/biawak.

Ecuadorian Research Expeditions

Dates for 2008 Ecuadorian Research Expeditions have been announced. These trips will take participants to western Ecuador to study reptiles and amphibians in some of the most imperiled ecosystems on Earth. This work provides vital data on rare and endangered wildlife that will help make informed management decisions and ultimately save them from extinction.

People from all walks of life and backgrounds are welcome to join us in the field. We are offering four expeditions this year, in January, June, July and August. New this year we have three back-to-back, two-week trips, and participants can sign up for one or any combination of them.

If you might be interested, check out these links. Also, please spread the word to your friends, colleagues, and students.

Kansas Herpetological Society Annual Meeting

The Kansas Herpetological Society held its 34th Annual Meeting at the Topeka Zoo in Topeka, Kansas, on November 2–4, 2007. Over 140 participants attended scientific paper sessions presented by scientists and students from across the nation. Featured speakers were Emily Moriarty Lemmon (University of Texas at Austin), and Jonathan Campbell (University of Texas-Arlington).

Melissa Boetig, student at Washburn University, received the 2007 Howard K. Gloyd/Edward H. Taylor Scholarship, honoring the memory of two great biologists with strong ties to Kansas. The 2007 Alan H. Kamb Grant for Research on Kansas Snakes was made to Page Klug, Kansas State University, Manhattan. J. Daren Riedle, West Texas A&M University, Canyon, was chosen as the tenth recipient of "The Suzanne L. & Joseph T. Collins Award for Excellence in Kansas Herpetology." George R. Pisani, Kansas Biological Survey at the University of Kansas, was installed as the ninth Distinguished Life Member of the Kansas Herpetological Society. In 2008, the Society will meet at Friends University, Wichita, Kansas.

Edward Elkan Memorial Lecture

This lecture commemorates the life and work of Dr. Edward Elkan who was medically qualified, had a life-long interest in comparative pathology and was a pioneer in the study of reptiles, amphibians and fish. Following Dr. Elkan's death in 1983, his microscope slides, gross specimens, books and reprints were put together as a teaching and research collection and a series of commemorative presentations was initiated—the Edward Elkan Memorial Lectures. The first four of these were given by Fredric L. Frye (USA), John E. Cooper (UK), Peer Zwart (The Netherlands), and Elliott R. Jacobson (USA). The fifth is due to be delivered by John Harshbarger (USA) in January 19, 2008 at the North American Veterinary Conference in Orlando, Florida, USA.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (rwh13@csufresno.edu) well in advance of the event.

7–9 February 2008—International Conference on the Coqui Frog, Waikoloa Beach Marriot Resort and Spa, Waikoloa, Hawaii, USA. Information: http://www.ctahr.hawaii.edu/coqui/conf08.asp

21–24 February 2008—SEPARC (Southeast Partners in Amphibian and Reptile Conservation) Annual Meeting, University of Georgia, Athens, Georgia, USA. Information: www.separc.org

11–13 April 2008—Fourth Annual Sonoran Desert Herpetological Symposium, Tucson, Arizona, USA. Information: http://www.arts.arizona.edu/herp/

5–7 June 2008—Joint Meeting of Texas Herpetological Society, SW PARC, Horned Lizard Conservation Society; University of Texas, Austin, Texas, USA. Information: gad.perry@ttu.edu

23–27 June 2008—6th Symposium on Lacertids of the Mediterranean Basin, Lesvos Island, Greece. Information: http://www.elerpe.org/

23–28 July 2008—51st Annual Meeting, Society for the Study of Amphibians and Reptiles; 88th Annual Meeting, American Society of Ichthyologists and Herpetologists; 66th Annual Meeting, The Herpetologists' League. Montreal, Quebec, Canada. Information: http://www.dce.ksu.edu/jointmeeting/

17–20 August 2008—6th World Congress of Herpetology, Manaus, Brazil (meeting jointly with SSAR). Information: http://www.worldcongressofherpetology.org/index.php?section=51

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Joshua Hale** or **Ben Lowe**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

Satellite Tracking of Migration in the Loggerhead Sea Turtle

Migration is important for species that rely on seasonally variable resources. The Atlantic Ocean off North America, has one of the world's largest populations of the loggerhead sea turtle, *Caretta carretta*; however, little is known about their migratory behavior. In this study, 12 adult female turtles were tracked for several years using satellite transmitters, and these data were combined with a number of oceanographic measures, including sea surface temperature, sea surface current and bathymetric data. Two different migration patterns were identified; the first involved northward migration in summer, extending 330–752 km from the nesting beach, and then southward migration in autumn. The second migration pattern was a southerly summer migration of 576–895 km from the nesting site, followed by winter residency in these sites. Of the 12 turtles monitored, nine migrated northward initially, exhibiting migration pattern one, and three migrated southward, exhibiting migration pattern two. Both these migration patterns allowed exploitation of warmer waters at the edge of the gulf stream. The satellite data also showed that turtles stayed largely in shallow waters (<100 m), which the authors suggest allows them to exploit benthic prey. Two turtles were also fitted with dive recording devices, and this showed that dive behavior at summer and winter breeding sites differed considerably, as dives in winter sites were of much greater duration. The authors suggest that the turtles may make long resting dives during winter, in a type of hibernation, and propose that this allows them to tolerate cold conditions while still taking advantage of productive waters. The authors highlight the need for further research that will be able to determine the frequency of the two migratory routes in the population and the selective pressures associated with them.

HAWKES, L. A., A. C. BRODERICK, M. S. COYNE, M. H. GODFREY AND B. J. GODLEY. 2007. Only some like it hot—quantifying the environmental niche of the loggerhead sea turtle. Diversity and Distributions 13:447–457.

Responses of Tuatara to Removal of Introduced Rats

Invasive predator species are generally thought to have negative impacts on endemic plants and animals, but specific hypotheses about their effects have not been widely tested. Tuatara, *Sphenodon punctatus*, are extinct from the New Zealand mainland, and are only found on smaller offshore islands. Three species of rat are common on these islands: Pacific Rats (*Rattus exulans*), which were introduced to New Zealand at least 750 years ago by Polynesians, and Norway (*R. norvegicus*), and Ship Rats (*R. rattus*), which were introduced by Europeans within the last 250 years. Tuatara do not coexist with either Norway or Ship Rats, but are found occasionally with Pacific Rats. In this paper, the authors investigated whether tuatara densities and recruitment are impacted by the presence of Pacific Rats. To do this, rats were eradicated from three of the Marotere Islands, northeastern New Zealand, and body condition and recruitment in tuatara from these islands were compared to those from the nearby Taranga Island, where rats are still present. These islands provide a unique opportunity for this type of study as they have restricted human access, have similar forest cover, and rats are the only predatory mammals. Following rat eradication, tuatara recruitment increased, with the number of juveniles growing by up to 17-fold. Additionally, body condition of adult males and females improved considerably. The authors conclude that the reduction in predation of eggs and juveniles following rat removal is an important factor in tuatara recruitment and body condition. They also suggest that more subtle interactions, such as competition for food, might also play some part in population growth, especially for a long lived species such as tuatara.

Evolution of Viviparity in Salamanders

The Fire Salamander, *Salamandra salamandra*, displays two reproductive strategies, viviparity and ovoviviparity, along its distribution on the Iberian Peninsula, which provides a unique opportunity to study the evolution of different reproductive modes. Ovoviviparity is the most common reproductive strategy in this species, but viviparity has been observed in a number of localities, including two small islands on the Atlantic coast that originated 8000–9000 years ago, after the last glacial period. In this study, the authors have sequenced approximately 1100bp of the Cyt *b* and *COI* regions on the mitochondrial genome from 1-15 individuals from each of 17 populations across the northern Iberian Peninsula, including both ovoviviparous and viviparous populations. Phylogenetic analyses revealed that the two viviparous

island populations do not form a monophyletic group with the mainland viviparous populations. Further, the authors suggest that it is unlikely that colonization of these islands occurred after they were cut off from the mainland, or that migration occurred between the islands. Therefore, the authors propose that viviparity has arisen independently multiple times, and conclude that this transition between reproductive modes can occur rapidly and often in island populations. The authors also discuss the ecological factors that may have led to the evolution of viviparity. As viviparity removes the need for water in the juvenile stage, a lack of water on these islands may be a factor for the evolution of this reproductive mode in island populations.

Sperm Storage Effects on Sex Ratio in Lizards

Female storage of sperm post-mating is common in a variety of taxa, and may be a response to rare mating opportunities or male sperm limitation. Although sperm storage has been widely studied, its influence on sex ratio remains relatively uninvestigated. In this study, the authors investigated the consequences of sperm storage in the Australian painted dragon lizard, *Ctenophorus pictus*. They brought field-mated females into the lab and then staged repeated matings with additional males to determine the contribution of 'fresh' versus 'stored' sperm. Fifty-four clutches resulted from matings between 34 females and 26 males, producing 180 offspring. Microsatellites were used to determine paternity, and offspring were then categorized as resulting from 'stored' or 'fresh' sperm. The average sperm storage difference between stored and fresh sperm was approximately two months. Results showed that stored sperm was 23% more likely to produce sons than fresh sperm. Similar temporal changes in sex ratio have been observed in a variety of taxa, including birds, rats, and humans, and as these taxa have different sex determining mechanisms, the relationship between sex ratio and sperm storage is likely to involve multiple factors. While the authors were unable to identify the proximate mechanism underlying the overproduction of males from stored sperm, they suggest that this mechanism may explain annual variation in sex ratio.

OLSSON, M., T. SCHWARTZ, T. ULLER AND M. HEALEY. 2007. Sons are made from old stores: sperm storage effects on sex ratio in a lizard. Biology Letters **Online Early: doi:10.1098/rbsl.2007.0196**

Communal Nesting in Montane Scincid Lizards

Females of the Australian montane scincid lizard, *Bassiana duperreyi*, oviposit communally, that is, they lay clutches within the same nests as other females. This communal nesting behavior is common in many reptile species, and may result from a lack of suitable oviposition sites (a constraint), or because females gain direct fitness benefits (an adaptation). In this study, the authors investigated whether communal nesting behavior represents an adaptation or constraint in *B. duperreyi*. In a field survey, the authors examined 367 nests over 11 years and demonstrated that communal and solitary nests were laid in similar sites, and were not related to the number of available sites. Further, investigation of 110 natural nests showed that incubation conditions did not differ between communal and solitary nests, or between eggs laid at the periphery and the centre of communal nests. This behavior was also investigated in a laboratory setting, with females laying 20 of 26 clutches in nests which contained dummy eggs rather than empty nests when four oviposition sites were available. Eggs laid in a communal setting absorbed less water and were larger than those laid in single nests, and furthermore, hatchlings from communal nests had shorter tails and ran quicker than those that were singly incubated. The authors suggest that communal nesting in this species is likely to be adaptive, and not due to a constraint in suitable breeding sites, however they suggest that this may be important in some species and in some conditions. While the authors propose that the fitness benefit of communal mating is likely to be due to the larger, faster hatchlings, the relationship of these traits with water uptake requires further study.

RADDER, R.S., AND R. SHINE. 2007. Why do female lizards lay their eggs in communal nests? Journal of Animal Ecology **Online early: doi: 10.1111/j.1365-2656.2007.01279.x**

Impact of Fragmentation and Colonization on Genetic Diversity in Frogs

Genetic diversity is an important component of population health, in particular, as an individual from a population with high diversity is expected to have higher fitness when compared to an individual from a low diversity population. Postglacial colonization from refugia and contemporary habitat fragmentation can both reduce population genetic diversity, but as they act at different temporal and spatial scales, their impacts may differ. In this study, the impact of postglacial colonization and habitat fragmentation on genetic diversity and fitness was examined in the Italian agile frog, *Rana latastei*, in the Lombardy in northern Italy. This species likely had one glacial refugium in the eastern part of its range, and as a consequence, genetic diversity is greater in populations from the east than from the west. Microsatellite diversity at 6 polymorphic loci was examined in 295 frogs from ten populations, four in developed environments ("isolated" populations) and six in riparian woodlands ("nonisolated" populations). To assess fitness, 7335 eggs were collected from 218 clutches and were reared to tadpoles in the laboratory before release in their wetland of ori-

gin. Results showed that distance from refugium and degree of isolation explained greater than 90% of the observed variation in genetic diversity. The lowest genetic diversity populations were those furthest away from the glacial refugium and from areas with high road density. Hatch rate was positively correlated with the isolation of the population, but only when the distance from the refugium was held constant. However, there was no relationship between hatch rate and genetic diversity. The authors propose that the reduced fitness in low diversity, isolated populations suggests that this process is ongoing and not directly related to the historical impact of colonization from refugia. Potential conservation implications of these results are also discussed.

FICETOLA, G. F., T. W. J. GARNER, AND F. DE BERNARDI. 2007. Genetic diversity, but not hatching success, is jointly affected by postglacial colonization and isolation in the threatened frog, *Rana latastei*. Molecular Ecology 16:1787–1797.

Distribution of Chytrid Fungus in Frog Populations

Amphibians are currently undergoing a well-documented decline, with a third of the more than 6000 species worldwide threatened. The chytrid fungus, *Batrachochytrium dendrobatidis*, infects the epidermis of amphibians and causes chytridiomycosis, a potentially lethal skin disease, and is often found at sites that are undergoing a population decline. Frogs display a variety of breeding strategies, from tadpole development in ponds or streams that may take years, to entirely terrestrial breeders. As the chytrid fungus cannot survive desiccation and has flagellated zoospores, it is unlikely that it would similarly impact frogs displaying different reproductive strategies. To test this hypothesis, the authors measured levels of chytrid infection in 19 frog species from southeast Queensland. Each species was identified as falling into one of five different breeding strategies; permanent stream, permanent pond, ephemeral stream, ephemeral pond and terrestrial. They found that 30.3% of the 519 individuals sampled were infected. Overwhelmingly, infected individuals were from species that bred in permanent streams and ponds, with ephemeral stream and pond breeders displaying no infection. There was only one terrestrial breeder sampled, and this species displayed very low levels of infection. The authors propose concentrating conservation efforts in relation to the chytrid fungus on frogs that breed in permanent waterbodies.

KRIGER, K. M., AND J. M. HERO. 2007. The chytrid fungus *Batrachochytrium dendrobatidis* is non-randomly distributed across amphibian breeding habitats. Diversity and Distributions **Online Early; doi: 10.1111/j.1472-4642.2007.00394.x**

Thermal Biology of Male and Female Lizards

Despite the considerable number of studies investigating the effects of body temperature on lizard physiology and ecology, these studies have generally not examined differences between sexes. As male and female lizards are often found utilizing different microhabitats and can be active at different times, thermally mediated differences in physiology and ecology may be important. In this study the authors reexamined a large data set which included 11,000 individuals from 56 desert species from Africa, Australia, and North America, to establish if sex differences in response to thermal conditions are present. Body temperature, air temperature, and daily activity times were compared between males and females from each species. Results showed that males and females had very similar body temperature (differing by less than 1°C on average), air temperature, and time of activity. The authors suggest that their large sample size ensured that small differences would have been detectable. Finally, the authors recognize that the very small differences between sexes in desert lizards may be an exception, and highlight the importance of investigating this in other lizard groups.

Lineage Identification of Captive Galápagos Tortoises

Genetic data are invaluable in the conservation of natural populations, but utility of these data in the conservation of captive populations has been relatively unexamined. The Galápagos tortoise, *Geochelone nigra*, is an endangered species, limited to only six islands of its historical 11 island range. Captive populations of this species are important, not only to prevent extinction but also as a source for reintroductions. Genetic data can ensure that inbreeding is avoided in captive populations and that appropriate individuals can be selected for reintroduction. In this study, 98 individuals of unknown origin were sampled from zoos and private collections across three continents. To compare the unknown individuals to previously sampled natural populations, a ~695 bp fragment of the mtDNA control region was sequenced for all individuals, and each was genotyped using ten microsatellite loci. Twenty mtDNA haplotypes were identified from the 98 captive individuals, with 14 of the haplotypes currently represented in natural populations. Population assignment results from microsatellite data were highly consistent with assignments from mtDNA data, with 83.7% of individuals assigned to the same extant population using both datasets. The authors suggest that those individuals for which microsatellite and mtDNA data assigned different ancestral populations are the result of shallow phylogenetic divergence among some taxa, or mixed ancestry in captive breedings. The majority of captive individuals came from populations on the islands of Isabela and Santa Cruz, and in particular

from the large and diverse La Caseta population on Santa Cruz. The results of the genetic analyses were also used to assess suitable breeding partners for the one surviving member of the Pinta population, Lonesome George, and determined that the two females currently housed with George do represent the most appropriate genetic matches.

Convergent Evolution in Drinking Adaptations in Two Desert Lizards

The Australian Thorny Devil, *Moloch horridus* (Agamidae), and the Texas Horned Lizard, *Phyrnosoma cornutum* (Iguanidae), are unrelated species yet are both able to drink by transporting water by capillary action through interscalar spaces on their skin to their mouth. In this study, the authors used scanning electron microscopy (SEM) and histological methods to examine the morphology of these interscalar spaces, or scale hinges, from both species, to investigate the potential for convergent evolution. Ventral scales were examined from 7 formalin-fixed *M. horridus* specimens and compared to 4 Australian agamid species. Likewise, 5 *P. cornatum* specimens were compared to 3 North American iguanids. The epidermis consists of two layers, the outer layer made up of ß-keratin, which is separated by a mesos layer from an inner layer made of α-keratin. In both species, each scale hinge has a semi-enclosed channel with convoluted walls, where the ß-keratin is very thin, which the authors call a hinge-joint channel. The authors propose that water is transported in these hinge-joint channels. Both species have a jaw-buccal cavity at the corner of the mouth, where jaw and tongue movements create negative pressure which promotes water flow to the mouth. Although there are slight differences in these structures between the two species, the authors suggest that the presence of these specialized structures, the jaw-buccal cavity and hinge-joint channels with convoluted walls, which are not present in closely related species, demonstrate that *P. cornatum* and *M. horridus* have undergone convergent evolution. They also conclude that this is most likely an adaptation to capturing water from temporally irregular rainfall events.

OBITUARIES

Herpetological Review, 2007, 38(4), 385–387.
© 2007 by Society for the Study of Amphibians and Reptiles

Maxime Lamotte (1920–2007)

ALAIN DUBOIS
and
ROGER BOUR
Reptiles & Amphibiens, Taxonomie & Collections
Systématique & Evolution, Muséum National d'Histoire Naturelle
CP 30, 25 rue Cuvier, 75005 Paris, France

Maxime Lamotte (Fig. 1) died on 31 August 2007 in Collobrières in southern France. He was born in Paris on 26 June 1920. After brilliant studies in the famous lycées Henri IV and Saint-Louis in Paris, then in the Paris Ecole Normale Supérieure (ENS), he obtained both his degree of "Docteur ès Sciences" and "Agrégé de l'Université" (the latter as "major" at the national level in France). In 1944 he was nominated as "Agrégé préparateur" in zoology at the ENS, in 1949 Assistant in genetics at the Paris University, in 1953 Professor at the University of Lille in northern France, in 1956 Professor at the Paris University and the ENS, and in 1988 Emeritus Professor at the Pierre et Marie Curie University in Paris.

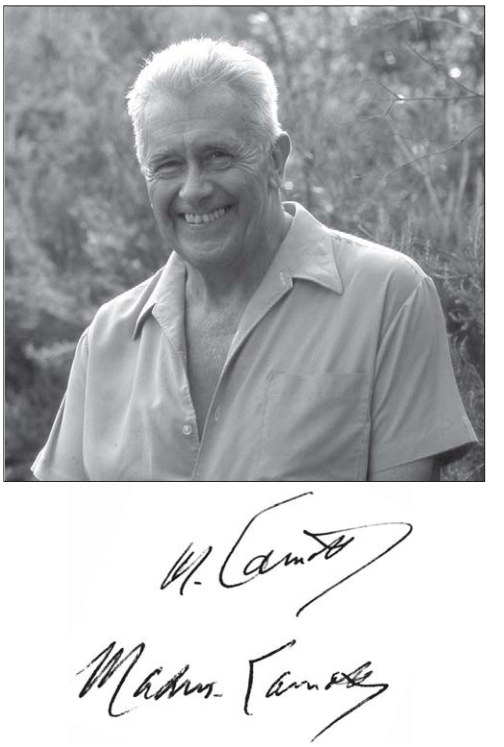

FIG. 1. Maxime Lamotte in Collobrières (Var), France, in August 1994 (photo Roger Bour). Lamotte's signatures, dated 3 November 1977 (upper, letter to Alain Dubois) and August 1994 (lower, book dedication to Roger Bour).

It is difficult to summarize his contribution to biology, as he was at the same time a theoretician, a field naturalist and an organizer of research. His thesis, defended in 1951 in the ENS, was dealing with the genetic structure of natural populations of the snail *Cepaea nemoralis*. In this work, he was the first to estimate allelic frequencies in many populations, in order to test the Sewall Wright models of Darwinian selection. In 1959, the results of this thesis launched the first large scientific polemics on the respective roles of random fluctuations (genetic drift) and natural selection in evolution, in a major symposium attended by Theodosius

Dobzhansky, Ernst Mayr, George Simpson, Bernhard Rensch, Leigh Van Valen, and Sewall Wright among others (*Cold Spring Harbor Symposia on Quantitative Biology*, 1959, 24:65–86).

His excellence in mathematics, as a pupil of Georges Teissier and a collaborator of Gustave Malécot, led him to write several textbooks of statistics. His *Introduction à la biologie quantitative* (1948) and his *Initiation aux méthodes statistiques en biologie* (1957) played a major role in the mathematical and methodological training and practice of generations of biologists in France and other French-speaking countries, especially in the fields of genetics, ecology and evolution.

His first travels in Africa on the Mount Nimba (Guinea), as soon as in 1942, developed his particular interest for the zoology and ecology of this continent. After administrative groundwork in 1961, he started with Jean-Luc Tournier the ecological field station of Lamto (named after the first letters of their names) in Ivory Coast in February 1962. In this station, he launched and supported many works on the quantitative and descriptive ecology of the forest savannas. These studies which dealt with many zoological groups, from earthworms to lizards, from spiders to crickets, fishes and birds, were also the basis for pioneer methodological works on sampling and data analysis in quantitative ecology, demography and productivity in terrestrial and aquatic habitats. He summarized some of these works, often in collaboration with François Bourlière, in a series of books (1967 to 1983) which were also a major source of training for many students and researchers in French-speaking countries.

From 1968 to 1994, he published several books about general problems of biology, dealing with the structure of the cell, sexual reproduction, laws and mechanisms of genetics, development and morphogenesis, and biological evolution. Several books published under his guidance by the Société Zoologique de France were particularly successful among the French-speaking zoological community: the volume *Le polymorphisme dans le règne animal* (1974) and the three volumes co-edited with Charles Bocquet and Jean Génermont and entitled *Les problèmes de l'espèce dans le règne animal* (1976, 1977 and 1980). As stressed by Ernst Mayr in his review of the first two of the latter books (*Systematic Zoology*, 1978, **27**: 250–252), it is a real pity that they were never translated and published in English, as they contain a unique synthesis of many works written in many different languages in various countries (including eastern Europe) and there exists no equivalent in English language. Other major publications by Maxime Lamotte include the three volumes of *Biologie générale*, co-authored with Philippe L'Héritier (1968), and *Théorie actuelle de l'évolution* (1994).

Beside being a theoretician, a mathematician, a methodologist, an organizer and a team leader, Maxime Lamotte was a very enthusiast field naturalist. All along his life, he collected specimens of many zoological groups in the numerous countries that he visited, and, after having kept them in the ENS for decades, he donated all these collections to the Paris Muséum National d'Histoire Naturelle (MNHN), where they will be available for study to researchers of the whole world. Although his first interests in this respect were insects, his discovery in January–July 1942 on the Mount Nimba of the extraordinary viviparous toad, described in 1943 by Fernand Angel as *Nectophrynoides occidentalis*, drew his attention, not only to this species and its very particular biology (on which he had many developmental, ecological and physiological works carried out by several students and researchers of his laboratory) but also on the other amphibians, especially of the Nimba and later of the Lamto region. With the collaboration of several colleagues, he was among the first batrachologists to pay attention to the tadpoles, as particular organisms worthy of interest for themselves, and to provide detailed descriptions of tadpoles referred to their proper species. He also worked on several groups of African ranids of difficult taxonomies, especially of the genera *Ptychadena* and *Phrynobatrachus*. Until his last years, he collected frog specimens, or had them collected, in various countries and habitats.

Maxime Lamotte was an exceptional teacher. He used a simple language to make even the most difficult questions accessible to many students. He was able to provide a clear presentation of any kind of biological subjects, even far from his own field of research. He had many students in genetics, population genetics, ecology, ecophysiology, physiology, and in taxonomy and evolutionary biology. Many of them are now prominent researchers or team leaders in various fields of biology in France and other countries. Maxime's hospitality and kindness were great, both with colleagues and students, either in the familial home in Paris, boulevard Raspail, or in the Collobrières house, and even in Lamto, where he invited a good number of researchers.

Maxime Lamotte was of the "old tradition" of research in French biology, in the sense that all his life he insisted to publish in French —although he could read easily other languages and understand the scientific literature in English, Spanish and German. Unfortunately, few of his works have been translated or summarized in English, and many are largely ignored by the English-speaking community—which nowadays almost covers the whole of the scientific community. This fate was in part avoided to his works in taxonomy and tadpole morphology, as reading these papers, even in French, is almost inescapable for anyone working on these questions, but the same is not true of many of his works in quantitative ecology, theoretical evolution and systematics, and even on the biology of *Nectophrynoides occidentalis*. Publication of summaries and syntheses of these works in English would be a useful endeavour.

Until his last days, Maxime Lamotte was an enthusiastic person. Although a bright mind, a famous biologist (who was among the youngest professors in biology ever in France and had received many distinctions, especially in France and Belgium), he always remained a very simple fellow. All along his life, he encouraged many young students, but also amateurs and persons interested in animals although they had not chosen to make zoology their profession, to develop their curiosity, their interest in life in the wild, or simple "natural history" studies based on hard field work, patient observations, careful specimen collection and preservation. He was more interested in the animals, their evolution, their adaptations, and in biologists contributing to understanding and knowing them better, than in honors, fame and power. As such, he was a bit unusual in his own community, especially in the last decades, as such matters seem to have become a priority for many. Long after his retirement, he continued to spend time at the MNHN, especially in the laboratories of entomology, herpetology and malacology.

Maxime Lamotte was very fond of the village of Collobrières,

in southern France (Var), that he had discovered, by chance, at the end of the fifties. He owned a house in the center of the village, in "Coppernic" street [sic], which was a preferred place for the holidays of his numerous family: Maxime and Françoise, his wife, had six children, followed by nineteen grandchildren and six great-grandchildren! Several members of this large family in their turn settled in Collobrières. An early riser, the naturalist would often take a walk in the hills of the Maures and the discovery of a treefrog in the vegetation along a small stream, or of a tortoise first heard in the bushes of the maquis, was always a new pleasure to him. The scientist could not help from examining the shell of a snail, or from reaping with large net casts a meadow full of orthopterans: all the equipment, net, boxes of all kinds, and even machete (!), was always ready in his great rucksack. The evils of age forced him to limit progressively the length of these walks, to his great sadness: Maxime would remain in the salon, sitting in his armchair, surrounded by books and his dear African masks, always glad to receive a visitor, parent or friend, under the attentive look of Françoise.

He will be regretted by all those who had the pleasure to share his experience, benefit from his courses, or from his friendship and his support to their own projects.

Center for Aquatic Ecology, Illinois Natural History Survey
Brighton, Illinois 62012, USA

Gary Paukstis, a life-long naturalist, died suddenly and unexpectedly on 5 July 2007 in Bellevue, Washington. Although he worked in sales of high-speed data communications equipment over the past 25 years, Gary nonetheless drew much of his professional identity as a scientist. He emphasized herpetological studies, publishing extensively on his research activities (his very first paper appeared in these pages 30 years ago [Paukstis 1977]) and contributing considerably to our field (N = ~ 60 publications).

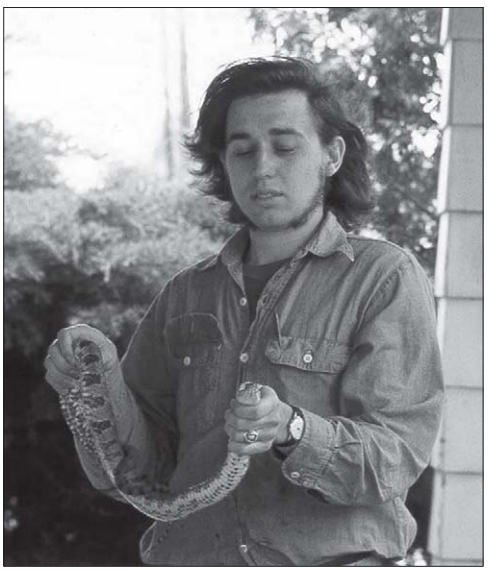

FIG. 1. Gary Paukstis holding a *Nerodia* in Illinois in 1974.

Gary Lynn Paukstis was born 1 February 1953, in Minneapolis, Minnesota. He lived in this area, as well as in Kansas and Wisconsin, for six years before his family settled for a long stretch in Hoffman Estates, Illinois. His father, Walter Paukstis, was a salesman and his mother, Edna Rosen Paukstis, was a piano teacher. Gary is survived by both of his parents, as well as his older brother Richard, his younger sister Donna, and their families. In addition to his wife Diane Bills Paukstis, Gary is survived by his children: Melissa, Hannah, and Christopher.

Beginning in 1971, Gary attended Illinois State University (ISU) intending to major in Music. But doubts about employability other than as a music teacher combined with a keen interest in biology led him to take courses in the sciences at ISU. It was a comparative vertebrate anatomy course taught by noted herpetologist Lauren Brown that inspired Gary to eventually change majors and join Lauren's fun group of students. Gary began as a volunteer who helped look after herps in the Brown lab (Fig. 1), but gladly accompanied the lab crew on herping adventures in Illinois and Florida and attended notable social events held at the Brown ranchero.

Upon graduation from ISU with a B.S. in Biological Sciences in 1975, Gary immediately joined the Brown lab formally to conduct graduate studies. During this time, Gary worked alongside, and occasionally roomed with, a strong cadre of herpetologically oriented students, including Richard Funk, Don Moll, and one of us (JKT), among others. Gary's M.S. work focused on variation in the intercalary cartilage as an important character for frog taxonomy, but he also joined in with members of the lab to explore all sorts of other interesting biological phenomena, primarily herpetological. Indeed, his years at ISU produced 10 publications on topics ranging from herpetological range extensions to invertebrate paleobiology, including a particularly influential paper concerning optimal egg size in turtles (Tucker et al. 1978).

After obtaining his M.S. in Biological Sciences from ISU in 1978, Gary joined Gary Packard's lab at Colorado State University (CSU) for Ph.D. studies. At CSU, Gary again struck up a number of productive collaborations in the Department of Zoology with other graduate students (most particularly William Gutzke in the Packard lab), leading to a series of significant publications, including some of the earliest experimental work on water relations of turtle eggs and temperature-dependent sex determination. Gary's dissertation research explored the roles of environmental variables in influencing the physiological ecology of turtle embryos and hatchlings in natural nests, yet he never completed his Ph.D. However, it was a semester-long return to CSU in fall 1985 that initiated another long-time productive collaboration, this time with a first-semester M.S. student in the Packard lab, the other one of us (FJJ). It was largely under Gary's influence that FJJ, an eager but very naïve student, learned many of the key unwritten rules of graduate school, scientific inquiry, and other important aspects of scholarly enterprise. At the same time, this budding friendship would prove crucial for maintaining Gary's research output.

Departing CSU in December 1985, Gary moved to northern Illinois to take a sales job with Okidata (and, subsequently, NEC

and, finally, Adtran) to be in the vicinity of his daughter Melissa. FJJ followed suit less than two years later, beginning Ph.D. studies at the University of Chicago in summer 1987. This immediate proximity initiated a rush of joint library, laboratory, and field research activities, initially focusing on aspects of sex-determining mechanisms in reptiles. Our collaboration produced a number of publications on this and other topics, including one of the top 20 most cited papers in the history of the *Quarterly Review of Biology* (Janzen and Paukstis 1991). We also undertook numerous herpetological adventures, primarily locally in northern Illinois, but also to the southern part of the state and to areas along the Mississippi River. These trips allowed us to indulge in some other shared passions, too: hunting, collecting baseball cards, listening to great music, drinking beer, immersing in natural history, and taking pictures (see http://www.garypaukstis.com for some of these), not necessarily in that order of preference. It was on a late 1980s trip that Gary helped FJJ found his long-term ongoing field site, known as Turtle Camp, in western Illinois. And it was on a trip to southern Illinois in the early 1990s that Gary introduced FJJ and JKT, generating 15+ years of a productive three-way research collaboration, including work on native gastropods and introduced zebra mussels (e.g., Paukstis et al. 1997) and a series of continuing publications on the evolutionary ecology of early life-history stages of turtles (e.g., Tucker and Paukstis 1999).

Then in 1998, Gary and family accepted a transfer from Adtran to take an equivalent sales position in the Seattle area. This move resulted in a dramatic decrease in Illinois fieldwork, but ultimately led to grander biological explorations and, in the end, to an important new chapter in his research activities and professional emphases. Gary and FJJ embarked on a series of major natural history adventures. Domestically, these trips emphasized the West Coast (his sales region with Adtran) and included an anxious physical encounter with a coral snake (*Micruroides euryxanthus*) in southern Arizona. Local medical personnel possessed neither antivenin nor correct knowledge of treatment, so the multihour drive to Phoenix was nerve-wracking to say the least. Internationally, these trips focused on Central and South America. Costa Rica was the most frequent destination, although a near-kidnapping by guerillas in remote Colombia was perhaps the most memorable experience, plus at least one anuran (*Osonophryne* sp.) encountered in Puracé National Park on that trip is almost certainly new to science (J. Savage, pers. comm., 7 December 2006).

Gary was just stepping into the next phase of his life, a return to science on a near full-time basis. He had retired from Adtran in 2006 with the expectation of decades of increased scientific productivity. He had turned his attention, in particular, toward serving the Organization for Tropical Studies (OTS) and writing field guides, activities that melded some of his favorite hobbies (exploring nature, taking pictures, working with people, etc.) with his strong business acumen. It is a testament to his skills in all these areas that he had already served on the Board of Visitors and then been elected to the Board of Directors (serving as Vice Chairman of Marketing and Development) of OTS, and had nearly completed the first (Paukstis et al., *in prep*.) of several planned field guides.

It was a great joy and honor to have known, and worked with, Gary. He was a man of many talents and interests. Beyond being intellectually creative and hard working, he possessed a keen, frequently employed wit, no doubt fed by his love of silly movies (the funniest of Woody Allen, Mel Brooks, and Monte Python, along with such fare as *Planes, Trains, and Automobiles*, *Wayne's World, Me, Myself, and Irene*, *The Three Amigos*, etc.). Gary also kept busy with numerous activities (some of which have already been mentioned), including tickling keyboards, constructing the Paukstis genealogy, playing tennis, spending time with his family, and hanging out at his cabin on the Olympic Peninsula (complete with a herp pond).

Gary would not have wanted a maudlin parting. Instead, we can envision him telling us all to get on with it in his own inimitable humorous style, likely quoting one of his very favorite movies, *Bill and Ted's Excellent Adventure*:

"Be excellent to each other……and party on, dudes!"

We will miss Gary greatly. Party on, dude, wherever you are!

ZOO VIEW

Fourteen of my colleagues and friends have been instrumental in my professional development and, through example and wise counsel, have expanded my view of the unlimited possibilities available for research, conservation biology, historical perspectives, and education within a zoo and aquarium environment. I have been most fortunate and wish to take this opportunity to thank them.

For nearly fifty years, Kraig Adler, Joseph T. Collins, and George B. Rabb have supported my interest in zoos and stressed the potential of these institutions to be an important subset in herpetology. They encouraged me to become involved in many professional herpetological societies, especially SSAR. Adler's unique understanding of the history of herpetology served as a significant model for my investigation of the evolution of zoos and aquariums.

For nearly forty years, Jonathan A. Campbell, William W. Lamar and Barry L. Armstrong have supported my vocation, been generous in providing a wealth of specimens collected throughout Latin America for the Dallas Zoo collection, and broadened my understanding of the herpetofauna in that region.

For over thirty years, David Chiszar has taught me that important biological questions can be answered through the design of simple, yet elegant, experiments. As an academic supportive of zoos, he has a critical understanding of the necessary interface between both communities and is ingenious as to how bonds can be formed between them. During this period, Harry W. Greene, Carl Gans, Hobart M. Smith, and the late Roger Conant challenged me to find better ways to use a zoo collection to learn about interesting animals doing interesting things.

Thirty years ago, Charles C. Carpenter and James C. Gillingham stressed the importance of zoo research and stimulated my interest in documenting amphibian and reptile behaviors by working with me on a number of projects in the beginning stages of my career at the Dallas Zoo. During the same time, Gary W. Ferguson showed me the proper way to examine lizards in the field and in captivity. Later, we traveled together to study chameleons, working on several projects to more fully understand the biology of these fascinating saurians.

New Book

"So general is the repugnance of mankind to the animals composing these classes, that their study has been overlooked, and they have usually been considered as beings which it was not only necessary but meritorious to destroy. A part of this vulgar prejudice is derived from education, and perhaps some of it may originate from the fact that several of them are furnished with venomous fangs, capable of causing intolerable sufferings and death. To the naturalist and physiologist, however; to those who study nature through her various modifications of form and structure, they present some of most interesting objects of contemplation. Their utility, either in diminishing various noxious animals, or in furnishing food themselves to others, has been lost sight of; and because they were cold to the touch, with a naked slimy skin without hair or feathers, they have been considered as loathsome and hideous, although their structure displays as much of the omnipotence and care of the Creator as can be seen in those which are considered to be the most gorgeous and beautiful of his animated beings."

—James De Kay in Preface to *Zoology of New York* in 1842

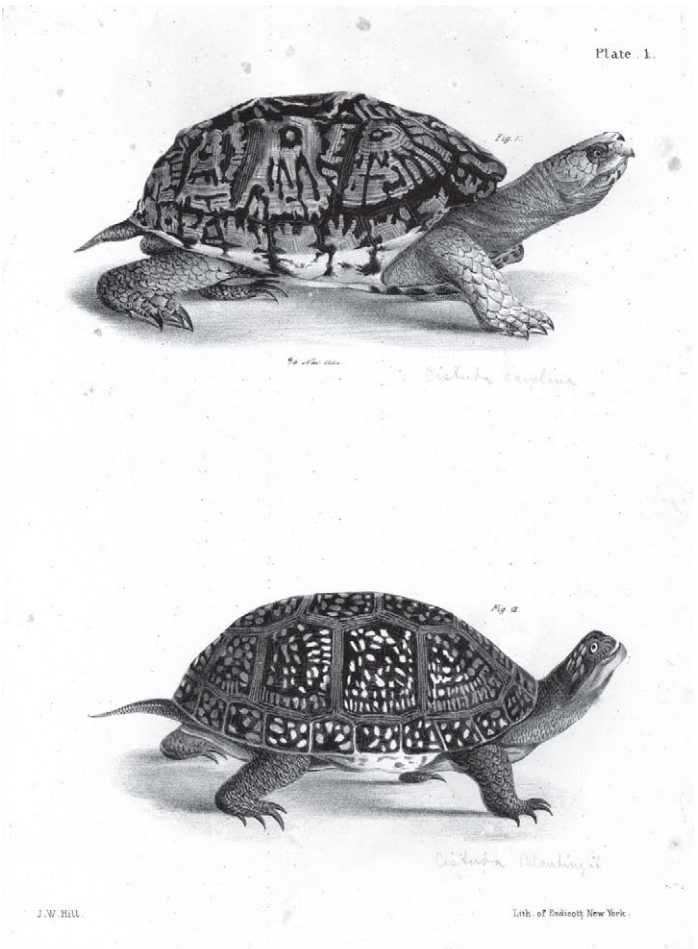
In 1842, James Ellsworth De Kay published *Zoology of New York* in the series Natural History of New York and even then was concerned about the loss of amphibians and reptiles due to human activity. This contribution was the first comprehensive study of the herpetofauna of New York State and included many striking illustrations by artist J. W. Hill (Fig. 1). Over a century and one-half later, another beautiful book on the amphibians and reptiles of that region has been published: *The Amphibians and Reptiles of New York State: Identification, Natural History, and Conservation* by James P. Gibbs, Alvin Breisch, Peter K. Ducey, Glenn Johnson, John L. Behler, and Richard C. Bothner (2007, Oxford University Press, New York; 72 color plates, 422 pp., ISBN: 978-0-19-530444-2). One of the authors, the late John Behler, was curator of herpetology at the Wildlife Conservation Society, headquartered at the Bronx Zoo (see Herpetol. Rev. 37:137–138) and this book is dedicated to his memory. Given that John was a committed conservation biologist, it is not surprising that this field guide emphasizes this aspect by including chapters on threats, legal protections, habitat conservation guidelines, and conservation studies. This is a terrific book, based on distributional data gathered for the New York State Amphibian and Reptile Atlas project (more than 60,000 records compiled between 1990–1999).

Cautionary Note

In an article entitled "Aquarium Science: Diagnosis of chytridiomycosis in pet African dwarf frogs," Barbara Scott and Jay Vance describe the chytrid fungus (*Batrachochytrium dendrobatidis*) found for the first time in commercially available African dwarf frogs (*Hymenochirus*) in the United States (Tropical Fish Hobbyist, 2007, vol. 45(11) #616:138–140). These frogs are commonly offered for sale in pet outlets and may be found in zoo collections.

Seaturtles in Captivity

Although seaturtles often are kept in large public aquariums,



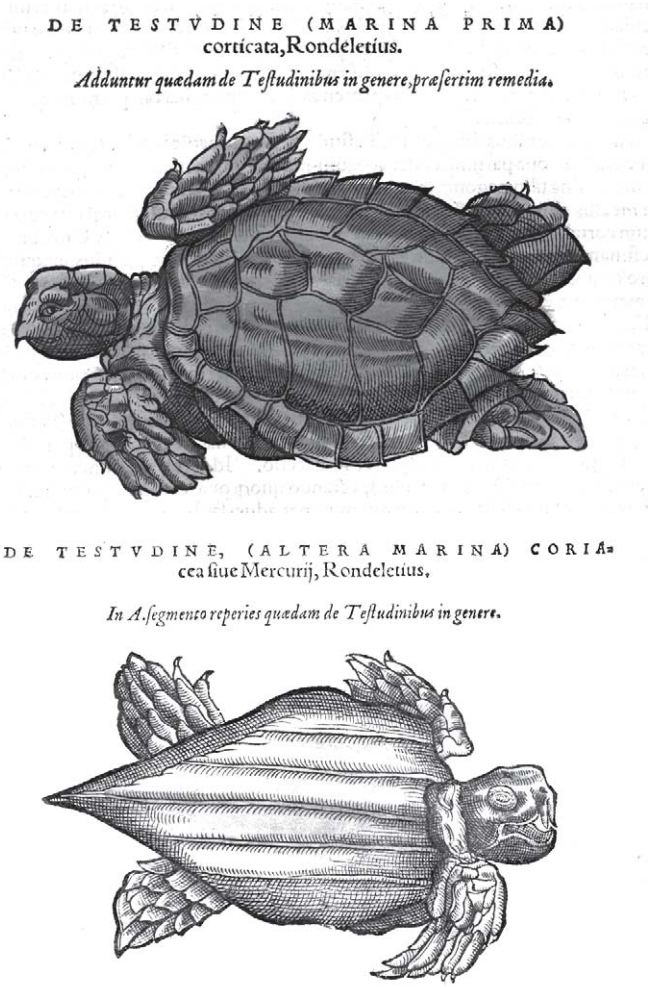


Fig. 1. Illustration of Eastern Box Turtle (Fig. 1, called *Cistudo carolina*, now *Terrapene c. carolina*) and Blanding's Turtle (Fig. 2, called *Cistudo blandingii*, now *Emydoidea blandingii*) by James Ellsworth De Kay. 1842–1844. Zoology of New York, or the New-York fauna: comprising detailed descriptions of all the animals hitherto observed within the state of New York, with brief notices of those occasionally found near its borders, and accompanied by appropriate illustrations. W. and A. White and J. Visscher, Albany, New York. Courtesy of Emily Becker, Dana Fisher, and James Hanken, collections of Ernst Mayr Library, Museum of Comparative Zoology, Harvard University.

Two views of seaturtles from the book by Konrad Gesner (= Conrad Gessner) in 1558. Woodcuts published during this period by Pierre Belon, Guillaume Rondelet, Joannes Jonstonus, and Nehemiah Grew often pictured chelonians with fangs, teeth, weird limbs, and bizarre shells with scutes (epidermal laminae) in the wrong places. In 1551, Gesner advertised in the preface of the first edition of *Historia Animalium I: de Quadrupedibus Viviparis* that hand colored copies were available "for customers who are not deterred by the higher price." *From:* Gesner, K. 1558. *Conradi Gesneri medici Tigurini Historiæ animalium liber IIII : qui est de Piscium & aquatilium animantium natura : cum iconibus singulorum ad uiuum expressis fere omnib. DCCVI. : continentur in hoc uolumine Gulielmi Rondeletij quoq[ue] medicinæ professoris regij in Schola Monspeliensi et Petri Bellonij Cenomanti, medici hoc tempore Lutetiæ eximij, de aquatilium singulis scripta. Tiguri : Apud Christoph. Froschouerum, 1558.* Courtesy of Emily Becker, Dana Fisher and James Hanken, collections of Ernst Mayr Library, Museum of Comparative Zoology, Harvard University.

they rarely breed in captivity. Most reports on management and reproductive behavior observed in captives have been written by Japanese researchers. Yoshioka and Samejima (1989) propagated the Loggerhead Seaturtle (*Caretta caretta*) at the Nagasakibana Parking Garden, Kagoshima, Japan. Uchida (1996) described indoor breeding of loggerheads at the Port of Nagoya Public Aquarium in Japan. Nuitja and Uchida (1982) followed growth and food consumption in juveniles. Oka et al. (1983), from the Shimonoseki Municipal Aquarium in Japan, kept the Leatherback Seaturtle (*Dermochelys coriacea*), a species difficult to maintain because of its specialized diet and pelagic habits. SeaWorld San Diego hatched 21 Green Seaturtles (*Chelonia mydas*) in 2003. In this issue, Ken Sakaoka, Makoto Yoshii, Hitoshi Nakamura, Kazuo Kureha, and Itaru Uchida from the Port of Nagoya Public Aquarium analyzed the reproductive behavior in captive *Caretta caretta*.

Amphibian chytridiomycosis has been recognized as an Emerging Infectious Disease by the World Wildlife Health Organization since 2001 (Speare et al. 2001). The causative agent, *Batrachochytrium dendrobatidis* ("Bd"), is a zoosporic fungal pathogen that has now been documented on all continents except Asia (Ouellet et al. 2005). Bd has been implicated as a causal agent in amphibian declines and extinctions in Spain (Bosch et al. 2001), South America (Ron et al. 2003), New Zealand (Waldman et al. 2001), Central America (Lips et al. 2005), Australia (Berger et al. 1998), California (Knapp and Morgan 2006; Rachowicz et al. 2006), Colorado (Muths et al. 2003; Carey et al. 2006) and Arizona (Bradley et al. 2002). Effects of Bd infection are species-specific (Davidson et al. 2003; Blaustein et al. 2005) and Bd pathogenicity may be affected by environmental factors (Drew et al. 2006), life history traits (Lips et al. 2003) or species biochemistry (Rollins-Smith et al. 2002; Woodhams et al. 2005, 2006). Bd has also been detected in two common laboratory species: *Xenopus*

tropicalis (Parker et al. 2002) and *Rana catesbeiana* (Mazzoni et al. 2003; Hanselmann et al. 2004; Garner et al. 2006). Some species are not clinically affected by Bd infection (Mazzoni et al. 2003; Davidson et al. 2003; Hanselmann et al. 2004; Garner et al. 2006) and thus can be carriers of the pathogen (Parker et al. 2002). While Bd in wild amphibian populations is of concern, attention also needs to be directed toward the potential for undetected Bd infection in commercially purchased amphibians used for laboratory research.

Herein we describe the chronology and events of a recent attempted pilot study, conducted at Southern Illinois University-Carbondale, Illinois, USA, in which we were using commercially harvested *Notophthalmus viridescens* (eastern newt) as the test species. Implementation of the pilot study was intended to finalize and troubleshoot the experimental design using a common species, prior to initiating the actual study on the target species, an endangered salamander from Texas, USA.

Three separate batches of *N. viridescens* were purchased from two well-known commercial vendors during Spring-Summer of 2006. The first batch of commercially purchased *N. viridescens* (N = 100, Batch No. 1) arrived on 20 June 2006. Animals in Batch No. 1 were immediately visually inspected for clinical signs of disease and were subsequently transferred to holding tanks (75.7 L tanks filled with 37.85 L of water) maintained in a room kept at 21.1°C ambient air temperature. Newts were randomly distributed initially between five tanks with 25 animals per tank undifferentiated by sex and were subsequently re-distributed into three tanks with 33 each in two tanks and 34 in the third. Behaviors were apparently normal and no specimens displayed any clinical signs of disease (e.g., excess skin sloughing, inappetance, lethargy or loss of righting reflex). Four days post-arrival numerous animals displayed excessive skin sloughing (Fig. 1), but were still active and eating well. Eleven days post-arrival two newts died. The dead animals had areas of focal hemorrhage on the latero-ventral surfaces and tail (Fig. 2). Fifty-two animals from Batch No. 1 died between 20 June 2006 and 21 July 2006.

Bd infection was initially diagnosed by David Green (U.S. Geological Survey) and the senior author (GEPF) via microscopic examination of wet mounts of sloughed skin samples. Total necropsy showed that no other pathogens were present. Bd diagnosis was confirmed by DNA analysis (Polymerase Chain Reaction, PCR, conducted at Pisces Molecular Laboratory, Boulder, Colorado; Boyle et al. 2002) following the methodology described in Annis et al. (2004) with some modifications. Changes in the method consisted of increasing the 35-cycle to a 45-cycle, increasing the annealing temperature from 15.6°C to 18.3°C, and also increasing [MG2+] from 1.5 mM to 3.5 mM (J. Wood, K. Rogers, L. Livo and J. Epp, ms. in prep.). Each PCR assay included controls of positive Bd DNA, negative Bd DNA and a contamination detection to ensure the Master Mix used was not contaminated.

The Bd PCR assay test is highly specific for the Bd ribosomal RNA Intervening Transcribed Sequence and the test is very sensitive as it will detect the presence of < 10 Bd zoospores in a 2µl sample (Annis et al. 2004). DNA analyses were conducted on pooled samples and therefore we have no indication of the prevalence of infection for any of the batches discussed herein.

A second batch of newts (N = 85, Batch No. 2) purchased from the same vendor arrived on 27 June 2006. Thirty-seven newts were placed in each of two 75.7 L tanks and 11 in a third 37.85 L tank. We experienced a similar sequence of events as described above and the first mortality occurred 10 days post-arrival. Ultimately 11 animals from Batch No. 2 died. Total mortality between Batches Nos. 1 and 2 reached 63 animals over a 30-day period.

FIG. 1. Commercially purchased *Notophthalmus viridescens* exhibited skin sloughing (arrows) four days after arrival at Southern Illinois University-Carbondale, Illinois, USA.

Notophthalmus viridescens purchased from a second vendor (N = 10, Batch No. 3) arrived on 6 July 2006. Batch No. 3 also tested positive for Bd via DNA analysis. This group was maintained separately [from Batches Nos. 1 and 2] and was held at 25.5°C. Animals in Batch No. 3 showed no clinical signs of disease (e.g., excessive skin slough) while being held at this temperature. On Day 22, five animals from Batch No. 3 were placed in a room kept at 21.1°C. Within eight days of relocation (Day 30 post-arrival at Southern Illinois University -Carbondale), this relocated subset displayed excessive skin sloughing. Mortality was observed 28 days later and eventually all five animals died. Animals in Batch No. 3 maintained at the higher temperature did not suffer mortality. To date, mortality in this third group was only observed in animals held at the lower temperature.

Wildlife and human-focused research commonly employ the use of commercially raised or harvested amphibians. Until our experience, scant attention was paid to the potential for Bd infection in commercially purchased research amphibians. The occurrence of

FIG. 2. Commercially purchased *Notophthalmus viridescens* exhibited numerous hemorrhagic areas, primarily located on the ventro-lateral surfaces and the tail (arrows), and began dying within 11 days of arrival at Southern Illinois University-Carbondale, Illinois, USA.

Bd in commercial research resources could have profound effects on research outcomes and may be particularly confounding when Bd is present but undetected. Results of studies on the effects of various treatments (e.g., contaminants, pesticides, UV exposure) may be confounded if the research subject is a species that can asymptomatically carry Bd; particularly if the experimental subjects have not been tested to verify they are Bd-free. In this scenario, conclusions about the treatment effects may be erroneous as the results could be related to the potential, yet largely unstudied, interaction(s) between the pathogen and treatment factor. Conversely, conclusions about treatment effects may be spurious as an observed effect may not be caused by the treatment or an interaction between treatment and pathogen, but may be a result of undetected, asymptomatic Bd infection.

Based on our experiences with these commercial research amphibians purchased from two different vendors, we recommend the following: 1) proposed budgets for research projects should include sufficient funding for maintenance costs during the quarantine period and for batched DNA testing for Bd; 2) all commercially purchased amphibians should be closely observed daily during a minimum quarantine period of 14 days; 3) quarantine areas should approximate the optimum temperature for Bd (17°C -23°C); and 4) pooled samples of these amphibians should be tested for Bd infection via DNA analysis prior to initiating the actual study.

Quarantine alone without DNA testing is likely insufficient to ensure that the group is Bd-free. Infection was present in all newt batches, yet Batch No. 3 was asymptomatic until a portion of the group was moved into a different temperature regime. In addition, the existence of carrier species which remain asymptomatic regardless of ambient air temperature, obviate the need for diagnostic testing. Given the financial, human and wildlife resources that are invested into research, the importance of reducing confounding variables in a study and the accurate interpretation of research results; it behooves us to take precautions to ensure that we are working with Bd-free animals.

Acknowledgments.—Gratitude is extended to the Barton Springs Salamander Conservation Fund and the City of Austin, Texas for funding provided as part of a larger project on the effects of PAH on salamanders. We would also like to thank Southern Illinois University-Carbondale (SIUC), the SIUC Institutional Animal Use and Care Committee (IACUC) and the Wildlife Co-operative Unit at SIUC for providing the permission, space and resources to conduct this work.

Size Record?

MARC P. HAYES
Habitat Program, Washington Department of Fish and Wildlife
Olympia, Washington 98501, USA
e-mail: hayesmph@dfw.wa.gov

DeVitt et al. (2007) recently published an interesting, yet most peculiar, maximum length record for *Pituophis catenifer*. As this record involves the maximum length for a native snake in the United States, it is of special interest to those for whom snake size maxima are an obsession, a condition which the disproportionate number of such records in snake literature reflects, and which has sometimes been humorously discussed (e.g., http://www.guardian.co.uk/g2/story/0,3604,1116074,00.html). Notably, DeVitt et al. (2007) report a "maximum" length following a captive interval of roughly two years, but curiously omit indicating the size of the animal at the time of collection. Even allowing that size at the time of collection was not obtained, and hence, unavailable, lack of understanding of the feeding regimen during captivity (not specified in DeVitt et al. [2007]) disallow this record as representing the maximum size that one might expect *P. catenifer* to attain in the field, and is inconsistent with Herpetological Review's primary guideline for Natural History Notes of "focusing on observations in field, with little human intrusion" (Hansen 2007). Furthermore, no presentation of growth data during the captive interval prevents potential contrasts with information on wild *P. catenifer* that might assist interpreting the size data presented, and is inconsistent with HR's secondary guideline for Natural History Notes of "possessing a natural history perspective" (Hansen 2007).

Briefly, it needs emphasis that this record only indicates the size that *P. catenifer* can attain in captivity, whether it does so in the wild remains to be seen.

Bacterial symbiotic relationships exist in several groups of vertebrates (Prem Anand and Sripathi 2004; Pryor and Bjorndal 2005; Pryor et al. 2006), and arthropods (Cazemier et al. 1997). Symbiotic bacteria in the gut ferment cellulose in plants and allow animals to digest the fatty acid byproducts of fermentative digestion. Bullfrog tadpoles, *Rana catesbeiana*, recently have been documented to benefit from fermentative microorganisms (Pryor and Bjorndal 2005) and this may exist for green frog tadpoles, *Rana clamitans*, as well. Tadpoles of both species feed by scraping various surfaces in the water and by filtering suspended food particles from the water, and their diet typically consists of algae, plankton, and detritus (Alford 1999). These tadpoles need to acquire large amounts of energy in order to undergo metamorphosis into frogs. *Rana catesbeiana* has one year to complete this change while *R. clamitans* can metamorphose within the same year as the eggs are laid, depending on multiple factors.

Fermentative digestion has recently been found in *R. catesbeiana* using methods that measured microbial activity in the intestinal tract by detecting the presence of short-chain fatty acids (Pryor and Bjorndal 2005). Bacteria, protists, and nematodes were detected in the intestine and appear to be involved in symbiotic digestion. We build on these results in our study. We used a staining technique to detect the presence or absence of cellulose on agar plates that housed colonies of bacteria taken from the intestines of bullfrog and green frog tadpoles. Our goals were to detect the presence of cellulose digestion in tadpoles of a second species (*Rana clamitans*), and to explore the range of conditions under which tadpole gut bacteria can conduct cellulose digestion.

Methods.—Larval anurans were obtained from ponds in Allen County, Ohio, USA, via dip netting or seining. Tadpoles were euthanized via saturated sodium benzocaine solution. The intestinal tract was removed in its entirety, or as close as possible, and macerated in 10 milliliters physiologic saline solution. Maceration continued until the solution was clouded. This solution was used to inoculate plates as described below. Individuals were pre-

served in 70% ethanol for later species identification (*Rana clamitans* and *R. catesbeiana*) and determination of larval developmental stage (stages 24–26; Gosner 1960). A total of eight tadpoles were used for this study.

Experiment one included growing cultures of inoculated plates in aerobic conditions on tryptone-growth agar (TGA) with added carboxymethylcellulose (CMC) for 48 h. This was to confirm fermentative activity in the gut bacteria, and used two tadpoles (*R. clamitans* only). Experiment two consisted of inoculating TGA plates with added CMC and glucose, and growing them in either anaerobic or aerobic conditions. This was to see whether the bacteria would grow using glucose or cellulose under anaerobic and aerobic conditions, and used four tadpoles (two each of *R. clamitans* and *R. catesbeiana*). Experiment three was a comparison of glucose and cellulose usage by the intestinal flora. This was done by inoculating four plates with a sample from a single individual. This was done with two tadpoles (*R. clamitans* and *R. catesbeiana*). The plates were all TGA with added CMC, two with glucose and two without. One plate from each of these pairs was grown in aerobic conditions; the other from each pair was grown in anaerobic conditions. This was done to see under what conditions bacteria grew the best, and utilized cellulose the most.

Agar plates were made using TGA (recipe from Stukus 1997), with variations upon this original recipe. Agar included trypticase soy broth, yeast extract, agar, and CMC (cellulose source, added to original recipe). In half of the agar, glucose was added to allow growth of non-fermentative bacteria. Agar preparation consisted of boiling distilled water for 10 minutes prior to the addition of constituent chemicals to kill most contaminants present. The agar was poured to desired thickness onto sterile, single-use plastic Petri dishes, and covered. Plates were then allowed to cool at ambient temperature until set, after which plates were refrigerated until use. Also, control plates were made that were the same as the experimental plates, to verify sterility of the broth and technique.

Prior to use, plates were allowed to equilibrate to room temperature. Inoculation consisted of tapping a grid of three dots by three dots or four dots by four dots (yielding 9 or 16 total dots, each with a diameter of approximately 1.0 cm) of inoculate and marking their location with permanent marker on the Petri dish. This method allowed a more controlled comparison, by identifying specific areas of the plate that had been inoculated, and eased in identifying fermentative activity due to bacteria. The other plating method was flooding of the entire plate with one milliliter of inoculate, with later streak isolation of individual colonies. This method served to grow the largest amount of bacteria per plate. All fluid was absorbed within one half hour in the flooded plates. Inoculate for all samples were drawn from throughout the column of sample and saline solution. All growth occurred at room temperature, for 48–72 h, with plates upside down to avoid airborne contamination. The plates were grown in both aerobic and anaerobic conditions. The anaerobic conditions were obtained by using an anaerobic growth chamber from Ward's Science (AnearoPack©, no. 50-25 (container) and no. 10-01 (ascorbic acid sachets and indicators)), including a chemical oxygen fixing sachet, and an indicator sachet using methylene blue. All trials showed positive for lack of oxygen with the indicator changing from pink or white (oxygen negative) immediately upon removal from packaging, to blue after oxygen exposure, and back to pink or white after the oxygen-fixing sachet finished working.

All plates showing growth were then treated with Congo red dye and hydrochloric acid to test for the presence of polysaccharides (i.e., cellulose). The dye binds to polysaccharides such as cellulose, but not the products of their degradation (Ruijssnaars and Hartmans 2000), leaving a halo of non-colored agar around areas of degradation. Bacterial plates were first flooded with saturated Congo red solution, then washed with 1 M NaCl, and finally rinsed multiple times with distilled water (Ruijssnaars and Hartmans 2000). Hydrochloric acid (1 M) was then added to increase the contrast by converting the Congo red dye from red to blue, for better photographic resolution and ease of analysis. All plates were grown for 48–72 h. Experiment four was solely a control experiment checking for the presence of oxygen trapped in the agar and in solution in the anaerobic chamber. Plain agar (non-nutritive agar and water only) was inoculated with methylene blue. These plates as well as a vial of methylene blue solution were placed in the anaerobic chamber and the chamber was set up as per manufacturer's instructions.

Results.—Bacteria isolated from both species of tadpoles showed cellulolytic activity on the agar plates. All four experiments showed cellulolytic activity (indicated by haloes after Congo red staining) in all the samples under aerobic conditions. These cultures also grew and utilized cellulose under anaerobic conditions in experiments two and three. Moreover, cellulose usage was increased under anaerobic conditions (experiment two), as indicated by larger halo diameters compared to those in experiment one. The most growth occurred on the glucose positive, aerobic plates, and the least growth on the glucose negative, anaerobic plates. Cellulolytic activity was best on the glucose negative, aerobic plates, and worst on the glucose positive, anaerobic plates. In addition, under anaerobic conditions, bacterial growth proceeded as not just across the surface of the agar, but also into the agar. Whereas atmospheric oxygen was removed from the chamber, oxygen may have been trapped in the liquid agar solution, and then in the solidified agar, thus not being removed by the ascorbic acid sachet.

Discussion.—We found that general bacterial growth was positively affected by the presence of glucose and oxygen, while cellulolytic activity was negatively affected by these conditions. It is very possible that intestinal bacteria used in our study are facultative anaerobic fermenters, and only resort to fermentation when necessary. This would be expected considering the lower amount of energy made available by anaerobic fermentation compared to aerobic respiration. The identity of the intestinal flora and their status as resident or transient microbes are not known at this time.

Endosymbiotic bacteria are fairly common throughout vertebrates, and may provide a significant source of additional nutrition for organisms that survive on a low-energy, high-cellulose diet. Ranid tadpoles have a diet of algae, detritus, and plant-based material (Alford 1999), with occasional carnivorous morphs observed (L. Regula Meyer, pers. obs.). Due to the high energy demands of metamorphosis and early stages of larval growth, individuals with an ability to utilize larger amounts of energy may have an adaptive advantage over individuals that do not. With the increasing prevalence of antibiotics in water sources because of the overuse and nondegradation of antibiotics, both human and veterinary, (Shinwoo 2004), any changes in intestinal flora may have growth and survival implications for amphibians. At a time

when amphibians are in decline globally, it is essential to understand what conditions are detrimental to amphibian survival, especially if those conditions are anthropogenic.

Further research is continuing in this area, including identification of the intestinal flora, testing the microbial response to various antibiotics, and any life history changes in individuals lacking endosymbiotic bacteria.

Acknowledgments.—We thank Ohio State University ILACUC for approval and oversight of this project, Jacob Dicus for the use of his pond, our reviewers for their comments, and Eric Juterbock for his encouragement and assistance. This project was funded by Ohio State Denman Undergraduate Research Fund.

Quantitative Analysis of Reproductive Behavior in Captive Loggerhead Turtles (*Caretta caretta*)

The large number of research projects on the reproductive ecology of sea turtles thus far has focused mainly on observations along the seacoast, concentrating on only several hours of the long life span of these turtles. Few studies have been made regarding courtship and mating in the wild due to the difficulty in observing these behaviors, particularly over a long period of time. Therefore, the temporal relationships between copulation, fertilization, and egg–laying in sea turtles remain unclear.

Although mating after the nesting period has been suggested in some early studies on Green Turtles, *Chelonia mydas* (Carr and Giovannoli 1957; Carr and Hirth 1962; Carr and Ogren 1960; Harrisson 1954; Hendrickson 1958), recent observational and satellite telemetry studies have shown that males of several species depart the breeding ground once the nesting period begins (Hays et al. 2001; James et al. 2005; Plotkin 1996). Furthermore, the peak of copulations of green turtles off the coast of Ascension Island coincides with that of female influx into the breeding ground (Godley et al. 2002). Such a temporal relationship between mating and nesting is in accordance with the hypothesis by Owens (1980) that female sea turtles copulate prior to the nesting period and store sperm during the reproductive season. Such a hypothesis is also supported by histological investigations of sperm storage organs of female reproductive tracts (Chaves et al. 2000; Gist and Jones 1988; Solomon and Baird1979). However, no study has investigated the relationship between mating history and reproductive success of individual female turtles in the wild.

We believe that research conducted in captivity, which enables observations on reproductive events of individually identifiable sea turtles, can elucidate behavioral aspects that are difficult to obtain in the wild. For example, in the Cayman turtle farm on Grand Cayman Island, British West Indies, male green turtles in a breeding pool were observed to mate most frequently approximately 30 days before laying the first clutch and no mating was observed after laying the first clutch (Simon et al. 1975; Ulrich and Parkes 1978). A similar pattern was observed in captive Kemp's Ridley Turtles, *Lepidochelys kempi* (Rostal et al. 1988). In addition, there existed a correlation between the duration of observed mating of female Green Turtles in a breeding pool and the hatchability of their clutch (Wood and Wood 1980). However, in studies conducted at night with poor water visibility and with a limited number of observers, it is conceivable that confusion in identifying individuals and behavioral patterns could occur, even dur-

ing long–term observations.

It is reasonable to assume that captive research would be even more beneficial under a system that enables quantitative and long–term observations of reproductive behavior. In the study reported here, we have utilized supersensitive cameras around the exhibit tank for a minute by minute, around the clock recording to conduct quantitative observations of mating behavior of captive Loggerhead Turtles, *Caretta caretta*. Our goals are to investigate the temporal relationship between mating and nesting, and relationships between mating histories of individual egg-laying females and fertility of their clutches.

At the Port of Nagoya Public Aquarium (PNPA), Nagoya, Japan, sea turtles are maintained in a doughnut-shaped exhibit tank (13 m in diameter, 2.5 m in depth, and 3.5×10^5 liters in tank volume) provided with a slow-moving current. Adjacent to the tank is an artificial dune (20 × 5 m) for the turtles to land and nest. During the study period, water temperature in the tank was regulated between 23° (winter) and 27°C (summer). A natural photoperiod was available through skylights above the tank. Between 1990 and 1993, a total of nine adult Loggerhead Turtles (four males and five females) were brought into captivity from the Sea of Kumano and Enshu off the coast of central Honshu Island and off the coast of Makurazaki in southern Kyushu Island. Also in the tank are three Loggerheads hatched from eggs collected on a beach in Hamamatsu, Shizuoka Prefecture in central Honshu in 1990. The Loggerheads are housed with Green (*Chelonia mydas*) and Hawksbill (*Eretmochelys imbricata*) turtles.

Two cameras were placed around the exhibit tank to monitor mating behavior of turtles in the breeding seasons of 2001 (1 November 2000 to 31 October 2001) and 2002 (1 January 2002 to 31 August 2002). These supersensitive cameras (Panasonic WV–BL734, Matsushita Communication Industrial Co., Ltd., Yokohama, Japan) were capable of providing images even in darkness at a minimum light intensity of 0.04 lx. Each camera was positioned to give the widest view with the lens directed toward the surface of the water. The range covered by each camera was about 3.0 × 4.0 m, aided at night by a spotlight with a 65 W mini halogen bulb with a red filter in order to minimize the effect of ambient light around the tank. Varying locations on the scutes of each turtle were painted white for accurate individual identification. Images during the 24 h period were recorded on S-VHS videotape using two time-lapse video recorders (Panasonic AG-6740, Matsushita Electronics Industrial Co., Ltd., Ibaraki, Japan). The elapsed period between images was 0.217 sec, rapid enough to record any behavioral sequence. Because the two cameras covered about one-third of the entire exhibit tank, we defined observed time per mounting as: 1) the interval from the start to the end of mounting if we observed these events using the cameras (including the time during which the mounting pair was out of sight); 2) the duration of observed time if we first observed an already mounted pair that subsequently moved out of sight (therefore, we observed the mounting pair only once); or 3) the interval from the start to the end of observation, or to the end of mounting if we first observed an already mounted pair and observed the pair intermittently. Furthermore, as each camera provided only an aerial view of the mounting pair,; we could not confirm whether penile insertion occurred during each observed mounting. Therefore, opportunistic observations were made by trained staff members in the aquarium (first, second, and third author) from the side of the exhibit tank to record copulatory frequency and duration.

Eggs laid by each female were excavated and transferred as a group to a hatchery near the aquarium. During the transfer the top of each egg was marked and firmly positioned to prevent turning. After eggs were weighed and measured, they were reburied in sand in artificial egg cavities, the bottom of which was at a depth of 50 cm. Each nest was surrounded by a fence so that we could identify where each group of hatchlings originated. During incubation the ambient temperature of the nests was maintained at approximately 29°C.

In order to calculate the fertility of each clutch, the number of emergent hatchlings from each artificial nest was counted. Three days after the last emergence of hatchlings, each artificial nest was excavated and dead hatchlings or unhatched eggs were collected. These unhatched eggs were opened and checked for embryonic development. In this study, fertility was defined as follows: fertility (%) = (number of emergent hatchlings + number of hatchlings that died before emerging from the nest + number of unhatched eggs with dead embryos if they could clearly be determined) / (clutch size) × 100. Since almost all the unhatched eggs had already decomposed in the nests, it was difficult to differentiate between infertile eggs and eggs containing dead embryos so decomposed eggs were arbitrarily categorized as infertile.

During the study period, four of the five females (F1, F4, F6, and F11) laid successive clutches (30 clutches in total; number of clutches per female per season, range = 3–5; clutch size, range = 37–118). The fifth female (F15) did not lay eggs at all during the study period. Among the four females, three females laid eggs in successive breeding seasons. At least two clutches from different females were deteriorated or lost during 2001 breeding season. One female suffered a prolapsed oviduct immediately after laying the third clutch and failed to nest for the rest of the season. However, using ultrasonography, it was confirmed that she retained mature follicles in the ovary. Another female laid a second clutch but in the exhibit tank rather than on land, so we were unable to retrieve her eggs. A total of 2217 hatchlings emerged from artificial nests in the hatchery, with incubation periods ranging from 50 to 67 days. The calculated fertility of each clutch ranged from 45.9% to 98.8%.

Quantitative observations using cameras confirmed that all egg-laying females were repeatedly mounted by multiple males, and that the peak of matings occurred prior to the nesting period (Fig. 1). Observed time per mounting through cameras showed an asymmetric distribution in which mountings lasting less than 10 min accounted for 69.9% of all observed mountings, and the frequency declined as the duration increased (median 3 min, interquartile range = 1–28 min, N = 623). On the other hand, the duration of mountings during which penile insertion was observed opportunistically was distributed normally (mean ± SD, 90 ± 43 min, N = 34). Cumulative time and the number of mountings observed through cameras are summarized in Table 1.

Among four instances of five successive clutches (F4 2001, F11 2001, F6 2002, F11 2002), fertility was not significantly different (Friedman test, $\chi^2 = 1.4$, d.f. = 4, $P = 0.84$; Fig. 2). For the three females that laid eggs in successive breeding seasons (F4, F6, and F11), fertility was compared between individual clutches of successive breeding seasons according to the cumulative time of

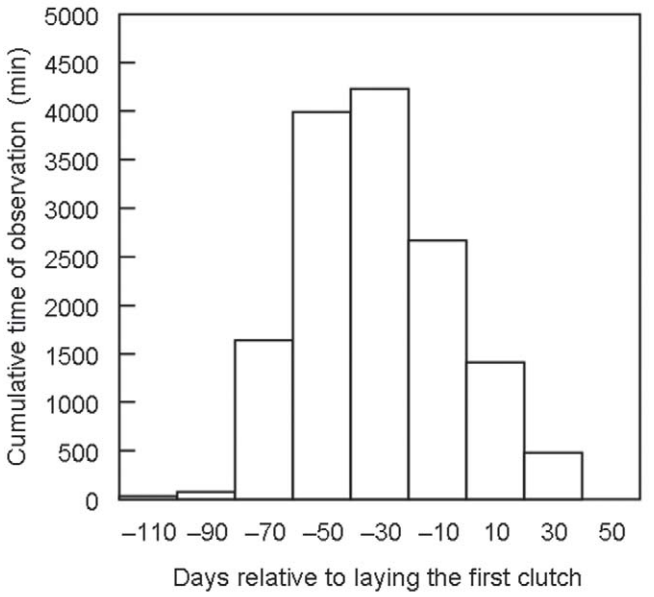

FIG. 1. Temporal distributions of observed time of mountings in loggerhead turtles under captive conditions.

mountings observed during the pre–nesting period (short vs. long, see Table 1). Fertility was not significantly different by the cumulative time of observed mountings (Wilcoxon matched-pairs signed-ranks test, $P = 023$; Fig. 3).

In this study, Loggerhead Turtles in the exhibit tank displayed a seasonal reproductive cycle in which the peak of matings occurred prior to the nesting period. Our work is based on a small sample size in captivity. Still, the findings concerning the relationship between mating and egg–laying are in general agreement with previous studies of several sea turtle species in the wild (Booth and Peters 1972; Godley et al. 2002; Hays et al. 2001; James et al. 2005; Plotkin 1996) and under captive conditions (Rostal et al. 1998; Simon et al. 1975; Ulrich and Parkes 1978; Wood and Wood 1980). Of special interest, in this study, there was no significant decline in fertility over successive clutches of individual turtles. These results indicate that females in the exhibit tank stored sperm during the breeding season and used it to fertilize successive clutches.

Because our observational method did not allow us to observe all the mountings occurred in the tank and evaluate reproductive success of each observed mounting, we could not compare the exact number of successful copulations among the egg-laying females. However, observed time per mounting through cameras and duration per copulation, during which penile insertion was observed by opportunistic observations indicate that there is a relationship between observed time per mounting and reproductive success. Wood (1953) observed a copulation bout by a pair of loggerhead turtle in captivity (during which insertion of the penis into the female's cloaca was seen) and reported that it lasted for at least 200 min. Dodd (1988) also suggested that copulation of loggerhead turtles lasts for several hours. On the other hand, shorter duration of mountings and attempted mountings observed frequently in this study have also been described in studies of green turtles with female rejection, such as circling or orientating toward an approaching male, and an attempt to dislodge a mounted male (Booth and Peters 1972; Hendrickson 1958; Wood and Wood 1980). Even if a male successfully mounted, the female sometimes covers her cloacae with the hind flipper to avoid penile insertion (Wood and Wood 1980). These findings indicate that majority of the shorter duration of mountings observed in this study were unsuccessful copulations during which female rejected penile insertion and that mounting needs to last for a given period of time to maximize reproductive success. Although, as mentioned above, our methods did not allow us to observe all the mountings that occurred in the tank, mountings which lasted for a long period of time were intermittently observed in the observational area, meaning that the probability of missing them was quite low. Taking these points into consideration, some females in this study may not have successfully copulated at all after laying the first clutch, and a female that was observed mounted with the shortest duration (F11, 2001 breeding season; cumulative time of observation, 128 min) may have successfully copulated only once during the breeding season.

Although there seemed to be a relationship between observed time per mounting and reproductive success, fertility was not significantly differentiated by the cumulative time of mountings observed during the pre–nesting period. Unfortunately, we could not explain this discrepancy using our experimental design. However,

TABLE 1. Cumulative time and the number of mountings observed through supersensitive cameras.

Female ID	Breeding season	Pre-nesting period					Inter-nesting interval				
		Cumulative time of observation (min)	Number of mountings (duration in min)				Cumulative time of observation (min)	Number of mountings (duration in min)			
			100	< 100	< 50	< 10		100	< 100	< 50	< 10

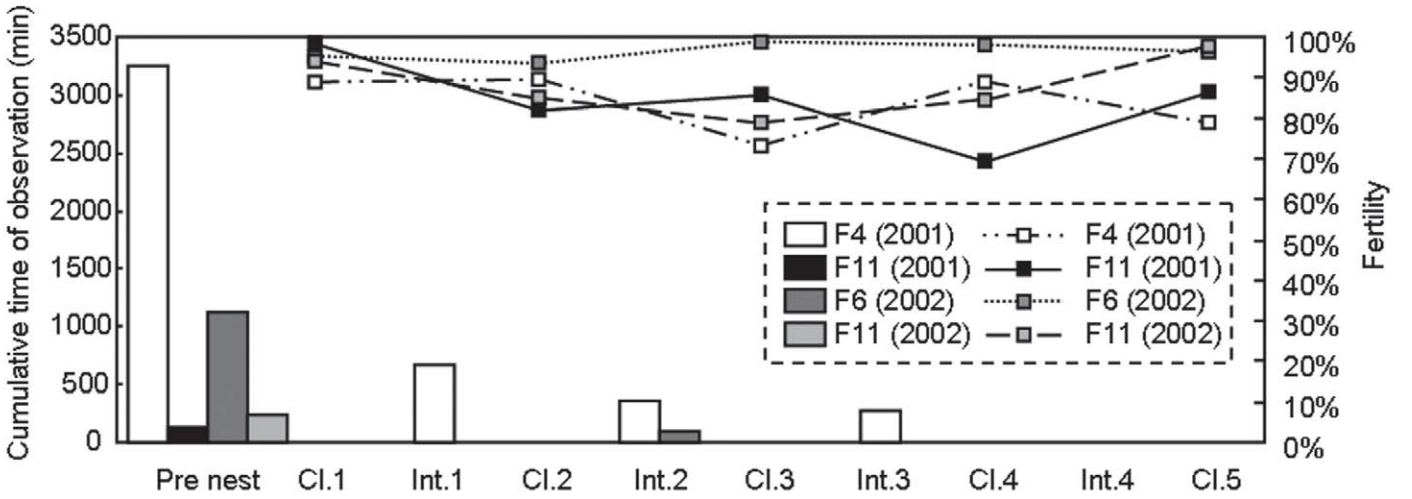

FIG. 2. Relationships between fertility of five successive clutches (line graphs) and temporal distributions of observed time of mountings (bar graphs).

we assume that this reflects the possibility that only a successful copulation could provide sufficient sperm to fertilize successive clutches, at least during a given reproductive season.

For the best understanding of the sperm utilization pattern to fertilize successive clutches, a method that directly evaluates reproductive success of copulations is indispensable. Recently, paternity analysis for hatchlings has been done in several turtle species (Bollmer et al. 1999; Crim et al. 2002; FitzSimmons 1998; Harry and Briscoe 1988; Hoekert et al. 2000; Kichler et al. 1999; Moore and Ball 2002; Parker et al. 1996). It is necessary to analyze paternity over successive clutches of individual female turtles and compare the mating history and paternity data to confirm how multiple copulations contribute to paternity and fertility over successive clutches, and whether copulations occurring during internesting intervals contribute to subsequent clutches.

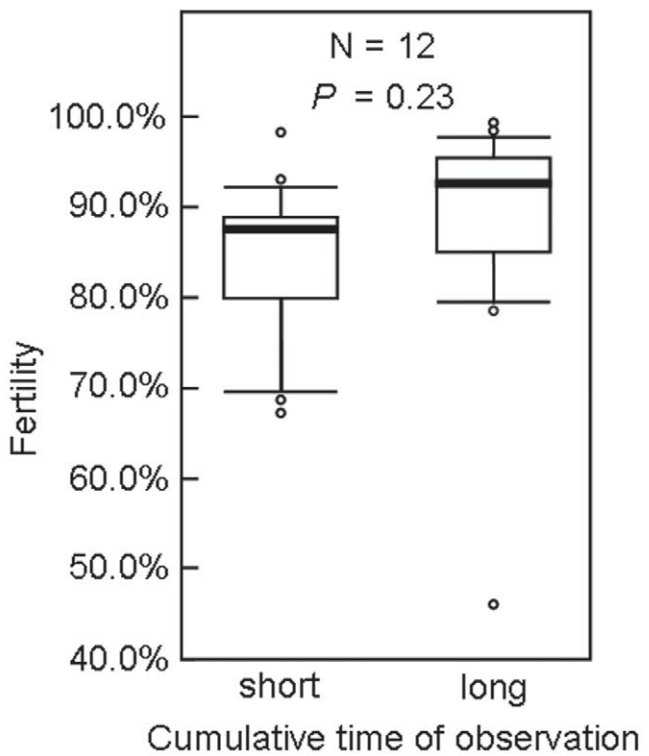

FIG. 3. Box plot comparison of fertility between individual clutches of successive breeding seasons according to the cumulative time of mountings observed during the pre–nesting period (short vs. long). The length of each box corresponds to the interquartile range, with the top boundary of the box representing the 75th and the bottom boundary the 25th percentile. The horizontal line in the box indicates the median value. The small bar at the end of the line extending upward from the box plot shows the 90th and downward 10th percentile. Outlier values are shown as open circles.

Acknowledgments.—We wish to express our appreciation to B. W. Bowen, D. Chiszar, J. B. Murphy, and K. Kawata for critically reviewing the manuscript. We also wish to thank K. Tsukamoto for helpful suggestions on the manuscript. We are grateful to T. Kato and other staff of the electrical facilities section of the Port of Nagoya Public Aquarium and the Nagoya Port Authority for their assistance with observation equipment. Thanks also go to the members of the sea turtle research group of the Tokyo University of Marine Science and Technology for their assistance with observing nesting females and collecting eggs. This study was partially supported by the International Resource Research Project of the Japan Fisheries Agency and the Japan Bekko Association. Adequate care of all the turtles in this study was taken by the technical staff of the PNPA. Capture of animals and experiments conducted in this paper comply with the current laws of the country (Japan) where they were performed.

For conservation and management of amphibians, it is now well recognized that aquatic and terrestrial habitats are essential to carry out life history functions of amphibians and that both habitats should be managed simultaneously (Semlitsch 2000). The amount of terrestrial habitat used during both breeding and post-breeding migrations, foraging, and overwintering defines the core terrestrial habitat of a population (sensu Semlitsch and Jensen 2001; Semlitsch 1998; Semlitsch and Bodie 2003), and is critical to the persistence of the local population. However, a better understanding of the habitats used for specific activities, and whether certain habitat types are being selectively used is also necessary. This is essential because it is often necessary to balance conservation needs for habitat protection with human landuse, and having more detailed information about the location of habitats essential for persistence is of great economic importance.

We present the results of a radio-telemetry study on four adults of the eastern tiger salamander, *Ambystoma tigrinum*, as they emigrate from a breeding site in South Carolina. We use the location of each individual to generate home ranges in the terrestrial habitat and maximum distance traveled away from the breeding site. We also provide limited data on the availability of habitat within the study area and within the home range of individuals.

Materials and Methods

Study site.—The study was conducted at a Carolina bay wetland called "Ellenton Bay" that serves as a major breeding site for many species of amphibians (Sharitz and Gibbons 1982; Gibbons et al. 2006). Ellenton Bay is approximately 10 ha in area, has a maximum water depth of 2.0 m, and was surrounded by agricultural fields until 1952. Since that time the terrestrial area has undergone succession and consists of primarily old fields (including powerline right-of-way), shrubs, and mixed pine-oak forest. These terrestrial habitats are xeric and consist of sandy, well-drained soils with patches of Sweetgum (*Liquidambar styraciflua*), oaks (*Quercus* spp.), Loblolly Pine (*Pinus taeda*), and Slash Pine (*Pinus elliottii*).

FIG. 1. Aerial photograph of the Ellenton Bay study area with minimum convex polygon home ranges (white cross-hatched areas, including emigration paths and connecting activity centers) of four salamanders.

Radio-telemetry.—The four salamanders were collected on 14 February 2000 at a drift fence with pitfall traps as they migrated to breed in Ellenton Bay. They were removed to the laboratory for implantation of radiotransmitters (model BD-2GH; 1.8 g; Holohil Systems Ltd., Ontario, Canada; 7.5–12% of the salamanders' body mass). Each salamander was placed in a 0.2% buffered solution of MS-222 (3-aminobenzoic acid ethyl ester) until unresponsive, rinsed with distilled water, and partially wrapped in a wet paper towel during surgery. Transmitters were inserted into the body cavity via a single longitudinal ventral incision to the right of the midline. Polygalactine 5-0 sutures were used to close both the abdominal muscle and skin. Individuals recovered from anesthesia 1–2 h after surgery. Salamanders were released within 48 h at their capture site on the inside of the drift fence. Upon emigration, individuals were captured leaving Ellenton Bay and were simply placed on the outside of the drift fence several meters in the presumed direction of travel.

We relocated individuals at least once a day for the first few days after release and then relocated them periodically until termination of the study on 24 May 2000. We used a four-band radio receiver (Model CE-12, Custom Electronics, Urbana, IL), with a three-element Yagi antenna (Model F151-3FB). Salamanders were located within 0.2 m, marked with a surveyor's flag, but left undisturbed either until no movement had occurred for several days or predation was suspected. Upon termination of the study, the three remaining live salamanders were retrieved and transmitters surgically removed.

Analyses.—The UTM coordinates of each relocation point were recorded using a backpack style Trimble GPS unit with submeter accuracy and imported into Arcview GIS (version 3.3; Environmental Systems Research Institute, Redlands, California). We estimated the home range of each salamander using minimum convex polygons (MCP, Animal Movements extension [Hooge et al. 1999] to Arcview). Net distance from the bay was also estimated. Habitat available to the salamanders was determined by encompassing the maximum distance traveled away from Ellenton Bay (~400 m) into an area approximately 800 × 800 m centered on the wetland. Habitat types within the available area (portion of Field 3-412 Set-Aside area extending ~400 m on all sides from the wetland edge) were classified by using a land-cover layer digitized from aerial photographs (old field-41%, scrub forest-7%, pine forest-31%, hardwoods-11%; Pinder et al. 1999). Salamander relocation points were overlaid onto the land-cover layer in ArcView to assign a habitat type to each salamander relocation. The devia-

*Movements are defined as migratory movements away from the site > 2.0 m

tion in relocation points from random use of available habitat was tested with a Chi-square test.

RESULTS

Salamanders were tracked for an average of 74.5 days and made an average of five long-distance terrestrial movements (Table 1). Between long distance movements, salamanders remained underground in activity centers with an area of < 1.0 m^2. At the end of the study, we found one salamander dehydrated on the leaf litter and three salamanders alive in tunnel systems running parallel to the surface, 8–10 cm underground, and about 2.5–3.0 cm in diameter. Terrestrial movements were in a direction that was generally perpendicular to the wetland edge and final locations were an average of 181.5 m (range 69.5–406 m) away from Ellenton Bay (Table 1; Fig. 1). The proportion of time spent in different terrestrial habitats was non-random with respect to habitat available in the area surrounding Ellenton Bay ($\chi^2 = 14.98$, df = 3, $P < 0.005$). In general, salamanders used pine and hardwood forest more than old field and scrub habitats.

DISCUSSION

The terrestrial migrations of Eastern Tiger Salamanders in South Carolina fit the pattern found for tiger salamanders in other regions (Madison and Farrand 1998; Steen et al. 2006), and for other pond-breeding ambystomatid species (e.g., Madison 1997; Semlitsch 1998; Rittenhouse and Semlitsch 2007). Generally, salamanders emigrate from breeding sites in a direction perpendicular to the wetland edge, initially make several long distance movements associated with rainfall events, and then settle into a small activity center within a few hundred meters of the wetland edge. Although female amphibians of some species are known to emigrate farther away from breeding sites than males (Rittenhouse and Semlitsch 2007), we were unable to test this difference with our limited sample size but the single female tracked traveled 406 m from the site. Individuals occasionally move to new activity centers, short distances (2–20 m) away. Activity centers were focal points of lateral underground movements < 1.0 m, similar to that previously described in more detail (Semlitsch 1981, 1983), and presumably used for feeding and remaining hydrated. The area encompassing emigration paths from the breeding site and connecting all activity centers, here defined as a home range, was relatively linear compared to typical reptilian or mammalian home ranges (Fig. 1).

In our study, tiger salamanders used forested habitat more often than open, old field habitats but the preference was variable among individuals. Notably, one salamander spent the entire tracking period (76 days) in old field habitat. Despite 3–4 rainfall events when the other salamanders moved further away from Ellenton Bay, male #47 made only short movements, remained in the old field habitat (in a waterline right-of-way), and was not desiccated or undernourished when retrieved at the end of the study. Similarly, Steen et al. (2006) reported the use of a wildlife food plot by one individual and a strip of trees between two food plots for another tiger salamander suggesting agricultural habitat did not constrain their movements. Yet, Madison and Farrand (1998) reported avoidance of grassy fields, paved roads, and commercial areas by tiger salamanders in New York. Although better resolution of habitat use is needed, these mixed findings might indicate that forest canopy cover may not be as critical to the persistence of tiger salamander populations in terrestrial habitats as the quality of soil and litter for obtaining adequate underground refuges. For example, the ability of salamanders to move underground by digging in loose sandy soils or by using rodent burrows may be the critical habitat feature. Substantial evidence now indicates a positive association between mole salamanders and rodent burrows (e.g., Loredo et al. 1996; Madison 1997; Madison and Farrand 1998; Regosin et al. 2003; Trenham and Shaffer 2005; Steen et al. 2006). Discrimination as to which habitat features are essential to population persistence, especially among different species, is a critical question for further research.

In conclusion, we suggest that Eastern Tiger Salamanders use large amounts of terrestrial habitat surrounding wetland breeding sites, similar to other ambystomatid species, and they rely on loose sandy soils and rodents to gain access to underground refuges. Thus, land use that truncates the size of this area or reduces their ability to retreat underground may jeopardize their population persistence.

Determining the sex of an individual is essential to many studies, from investigations of ecological and evolutionary processes to molecular studies of gene expression and biochemistry. For some lizards, sexual identification is straightforward because of differences in external dimorphism between the sexes (e.g., sexual dichromatism, enlarged postcloacal scales, femoral or precloacal pore morphology). In other species, visible sexual dimorphism can be subtle or absent. Only about 18% of lizard species are sexually dichromatic, with fewer than 10% of geckos, skinks, and chameleons exhibiting sexual differences (Cooper and Greenberg 1992). Even diagnostic traits like body size or pore morphology can vary seasonally, behaviorally, or environmentally due to body condition, and thus may be ambiguous under certain conditions. Additionally, sexing juveniles of dimorphic species can be difficult if diagnostic sexual traits have not yet developed. In these situations, researchers traditionally rely on the identification of the gonads (usually postmortem) or invasively verify the presence of hemipenes to accurately determine sex.

Hemipenal verification is usually accomplished by probing the cloaca with a small, blunt-tipped rod to measure the depth of insertion or "popping" the hemipenes by manually everting them via manipulation of the tail base (Stebbins 2003). However, invasive procedures can cause permanent damage to the cloaca or hemipenes, especially when performed by novices. Even experienced herpetologists will occasionally cause tail loss or stress a lizard during invasive sexing methods. These techniques are even more difficult if the animals are small. Here we describe a noninvasive method using light to sex lizards based on our studies of a small, sexually monomorphic lizard (*Xantusia vigilis*), and we show the technique's applicability for four other species (two iguanians and two gekkonids).

Xantusia vigilis (Desert Night Lizard) is a viviparous lizard that inhabits the deserts of the southwest U.S. and Mexico and is often found under rock or fallen *Yucca*. Adult lizards average 43 mm snout-vent length (SVL) and 1.5 g, whereas neonates average 23 mm SVL and 0.25 g at birth (Zweifel and Lowe, 1966; Davis, unpublished data). Because of its small size and lack of sexual dichromatism, sexing this species using traditional methods has been challenging (Miller 1951; Zweifel and Lowe 1966).

Zweifel and Lowe (1966) sexed *X. vigilis* by evaluating the shape of the thigh in cross section and by comparing the SVLs of older adults. Females often have more rounded thighs (see also Stebbins 2003) and can achieve a maximum size 3–4 mm greater than males by about 7–8 years of age. Additionally, Zweifel and Lowe (1966) noted that many postnatal females have conspicuous skin folds along the abdomen that are usually absent in males, but females rarely give birth before 3 or even 4 years of age. Thus, Zweifel and Lowe's method has two major drawbacks: 1) it is difficult or even impossible to use with juvenile and young adult lizards, and 2) all three diagnostic criteria are influenced by fluctuating environmental conditions (e.g., food availability), decreasing the reliability of their method. The new sexing technique we describe below, especially in combination with Zweifel and Lowe's criteria, will allow researchers greater confidence in sexing *X. vigilis* across age classes and environmental conditions.

To sex *X. vigilis*, we first grasp the lizard underneath the forelimbs so the ventral body surface is visible. Next, we position a bright, focused light source (e.g., Maglight® Solitaire® penlight or any small LED light) behind the dorsal side of the tail to direct a focused beam of light through the tail base (Fig. 1). The light allows us to visualize internal anatomy and examine the tail base for evidence of hemipenes. Female lizards have no obvious subcutaneous structures (Fig. 1A), whereas males have paired red dots or ovals in the location of the hemipenes and dorsoventral thickening of the tail base (hemipenal bulge; Fig. 1B, C). The visibility of dots varies and probably depends on blood flow to the region, but one can always see the dorsoventral thickening of the tail base in males, which is more apparent when illuminated.

Both authors independently sexed the same 20 adult *X. vigilis* with this light technique, agreeing on the sex of 19 individuals. From this set, we randomly chose and dissected five presumed

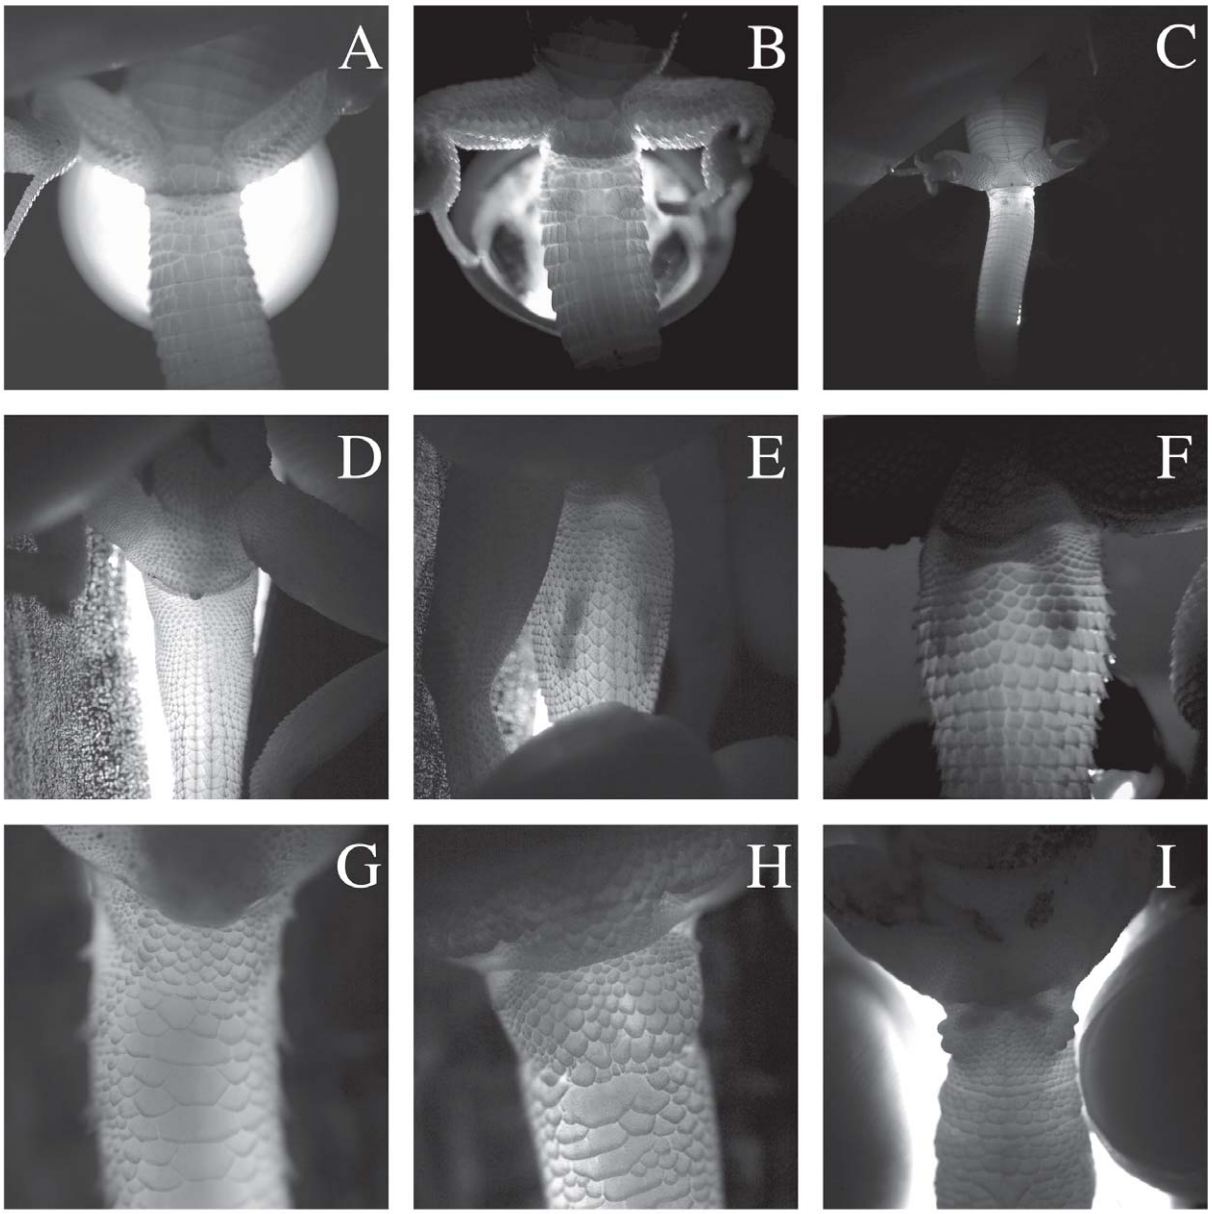

FIG. 1. Visualization of hemipenes by passing a bright condensed light through the tail base of males. Note that no such structures are visualized in females. (A) adult female *Xantusia vigilis*, (B) adult male *X. vigilis*, (C) neonate male *X. vigilis*, (D) adult female *Anolis wattsi*, (E) adult male *A. wattsi*, (F) adult male *Uta stansburiana*, (G) adult female *Hemidactylus mabouia*, (H) adult male *H. mabouia*, (I) adult male *Tarentola delalandii*.

males, five presumed females, and the contested individual to examine the gonads. These lizards were preselected for euthanasia for a separate project, and thus we viewed their dissection as an opportunity for a definitive test of our methods and not the motivation for it. The dissections revealed that all 10 of the randomly chosen individuals were sexed correctly using the light method and that the contested individual was a male. The single discrepancy likely resulted from a 10-fold difference in experience between the authors in sexing *X. vigilis* using this technique.

As further evidence for the repeatability of this method, we have captured, sexed, and uniquely marked over 1200 lizards in the field as part of a mark-recapture study. This sexing method has worked accurately through three years of study, across seasons, body conditions, and levels of melanism. Of the 156 lizards that have been captured more than once, only 11 have been assigned a different sex upon recapture (Table 1). There was no bias in the direction of the 11 sexing inconsistencies (N = 5 sexed initially as male, then female; N = 6 sexed initially as female, then male). Large lizards (38 mm SVL) were always assigned the same sex upon recapture , but even neonates (25 mm) were sexed fairly consistently (73%). Although neonates are the most challenging to sex because of their small size, hemipenes are still visible in many males (Fig. 1C).

As a preliminary test of the applicability of this sexing method for other lizard species, we illuminated tail bases in lizards from four additional species: two iguanians (*Uta stansburiana*, N = 15 females and 15 males; *Anolis wattsi*, N = 3 females and 4 males) and two gekkonids (*Hemidactylus mabouia*, N = 3 females and 2 males; *Tarentola delalandii*, N = 2 females and 2 males). Sexes were secondarily verified via external morphological characters (spurs, coloration, postcloacal scales) where applicable. Females in these species had a tail-base morphology similar to female *X.*

TABLE 1. Repeatability of sexing for *Xantusia vigilis* as a function of body size over a three-year study. SVL is size at first capture.

SVL (mm)	Approximate age (years)*	N recaptured	N (proportion) sexed identically
25	0	30	22 (0.73)
26–32	1	4	3 (0.75)
33–37	2	15	13 (0.86)
38–41	3–4	34	34 (1.00)
42–45	5–7	51	51 (1.00)
45	8+	22	22 (1.00)
TOTAL		156	145 (0.93)

* After Zweifel and Lowe (1966)

vigilis (Fig. 1A), within which no subcutaneous structures were visible (female *A. wattsi*, Fig. 1D; female *H. mabouia*, Fig. 1G; female *U. stansburiana* and *T. delalandii* not shown). Hemipenes in the males were clearly visible, although hemipenal morphology varied among species (Fig. 1E, F, H, I).

The strengths of this technique lie in the ability of researchers to sex individuals with high accuracy, at low cost, with little time investment, and with minimal contact with the lizard. The single discrepancy between the authors in sexing an adult *X. vigilis* and the increased difficulty in sexing neonates show that it takes practice to master the technique, but even investigators with little experience can sex lizards with high accuracy.

The successful use of this technique on species other than *X. vigilis* suggests that it may be widely applicable. Because dense melanin or extremely thick tissue may impede the passage of light through the tail, ideal candidates for use with this technique include other small, moderately pigmented lizards or small snakes (e.g., *Leptotyphlops* sp.), as well as juveniles of other squamate species. We encourage using this method in conjunction with other sexing techniques (e.g., scale or pore morphology, differences in dorsal pattern) on species with subtle dimorphism.

Acknowledgments.—We thank S. Adolph for the idea to shine a penlight through female *X. vigilis* to determine litter size, which led to the use of this method for sexing purposes. We would also like to thank B. Coupe for helping with the first few trials of this technique and attempting to double-check this procedure through probing. We thank R. Bezy for help collecting *X. vigilis*, giving feedback on the feasibility and application of this technique, and offering the title of the manuscript. We also thank W. Wüster and C. Pook for helping us photograph the captive *T. delalandii*, and the St. Lucia Forestry Department (D. Anthony, L. John, M. Robb) for permission to catch and photograph St. Lucian species. We give A. Corl, M. Mulks, and especially Y. Surget-Groba photography credit. Finally, we would like to thank A. Corl, M. Goode, S. Kuchta, H. Mostman-Liwanag, J. Richards, B. Sinervo, and an anonymous reviewer for helpful comments on this manuscript. California Department of Fish and Game collection permits (SC-05560) were issued to A. Davis, and methods were approved by the Chancellor's Animal Research Committee (Sine00.02-1) at the University of California, Santa Cruz.

Within the last three decades, techniques for age determination in amphibians of the temperate zone have converged on a most accurate predictor of age, i.e., skeletochronology, in which lines of arrested growth (LAG) are counted in bone tissues (Halliday and Verrell 1988). In skeletochronological approaches, one LAG corresponds to one annual period of arrested growth, i.e., hibernation or winter-dormancy (Francillon-Vieillot et al. 1990). Most of these approaches have been conducted using femurs (hindlimbs), humeri (forelimbs), and/or phalanges (toes) of individuals which were captured, killed, dissected, and fixed during the aquatic phase of the breeding season (Alcobendas and Castanet 2000; Caetano and Leclair 1996; Diaz-Paniagua and Mateo 1999; Forester and Lykens 1991; Marunouchi et al. 2000; Misawa and Matsui 1999; Verrell and Francillon 1986) or during the larval stage (Bruce and Castanet 2006).

Although toes clipped for capture-mark-recapture (CMR) studies had previously been discarded (e.g., Huheey and Brandon 1973; Hurlbert 1969; Kusano 1982), for skeletochronological approaches, a few studies have exploited phalanges of the toes clipped from live individuals captured during the terrestrial phase of the breeding and nonbreeding seasons (Diaz-Paniagua et al. 1996; M. Hasumi, unpubl. data). Independent of CMR studies, several recent studies have used toes clipped from live individuals for skeletochronology (Bovero et al. 2003; Ento and Matsui 2002, third toes were clipped besides toes clipped for a CMR study; Kusano et al. 2006; Miaud et al. 2001). When dealing with a great number (occasionally > 500) of small-sized toes or other appendages in many studies of caudate amphibians, it can be difficult to section frozen samples quickly and skillfully with a cryostat (Bruce and Castanet 2006; Diaz-Paniagua and Mateo 1999; Ento and Matsui 2002; Kusano et al. 2006; Miaud et al. 2001; Misawa and Matsui 1999; Verrell and Francillon 1986).

As a more efficient method, we recommend a traditional paraffin-embedding method, but this involves some problematic issues. Muscular tissues, especially the muscle sheath, surrounding phalanges of the toes clipped became brittle during tissue dehydration, and thus while it was possible to section the toe itself, the brittle sections including muscle tissue often separate from glass microscope slides during staining procedures. Hence, the muscle tissue should be removed prior to sectioning phalangeal bone tis-

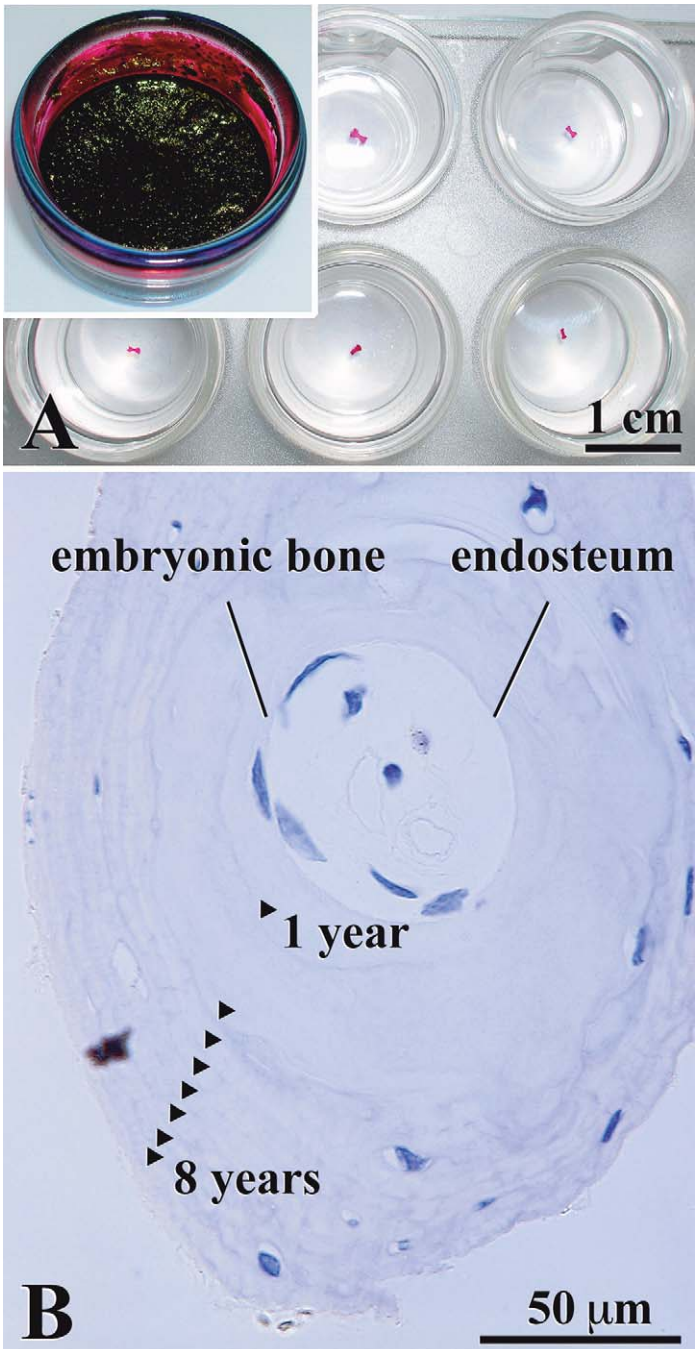

FIG. 1. A) Phalanges colored purple-red with acid fuchsine in the second 100% ethanol during tissue dehydration (note the indissolubility of acid fuchsine in alcohol), and viscous semi-dried acid fuchsine in water (upper left). B) A final product of a phalangeal bone processed using the method described here. Sample from an adult male *Salamandrella keyserlingii* (Kushiro Marsh, Japan) was sectioned transversely at 8 μm. Eight lines of arrested growth (LAG) and dense LAGs outside of a 2-year ring are visible. LAGs reflect yearly hibernation or winter-dormancy of animals in the temperate zone. Endosteal resorption of the innermost LAG (Eden et al. 2007) was not observed. Note the absence of both surrounding muscle tissue and acid fuchsine staining in the final product.

sue. However, if muscle tissue is completely removed, then it becomes difficult to identify and orient the remaining white-colored phalanx within the white-colored paraffin-embedding matrix. To solve these problems, we provide here the following unique method that one of us (MH) has utilized extensively for skeletochronology in hynobiid salamanders. This method involves removal of muscle to enhance adhesion of sections to microscope slides, and reversible staining of bone so that samples can be properly oriented in paraffin blocks.

PROCEDURE

Part I

(1) Fix clipped toes in 10% neutral buffered formalin; store samples from each individual in 1.5 ml microcentrifuge tubes. Neutral buffered formalin (10%) is recommended as the best fixative of bone tissue (Lillie 1976).

(2) Remove surrounding muscle tissues under a stereoscopic microscope after immersing samples in 2–4% potassium hydroxide (KOH) solution for 24 h or more.

(3) Decalcify phalangeal bones in 5% formic acid (HCOOH) solution or 5% nitric acid (HNO_3) solution for 1 h or more.

(4) Neutralize and stabilize phalanges in 5% sodium sulfate (Na_2SO_4) solution for 1 h or more to recover stainability.

(5) Preserve phalanges in 70% ethanol. Samples can be stored at this stage for long periods of time (more than 2–3 years).

Part II

(1) Dehydrate phalanges through a graded series of ethanols (70–100%) followed by xylenes for paraffin infiltration and embedding. Stain each phalanx purple-red with acid fuchsine (semi-dried, dissolved in water) between immersions in the 95% ethanol and the first 100% ethanol during tissue dehydration (Fig. 1A). A thick, viscous solution of semi-dried acid fuchsine will stain the entire phalanx.

(2) Embed dehydrated tissues in paraffin (Paraplast: Sherwood Medical Co., St. Louis, Missouri, USA).

(3) Section tissues transversely at 8–16 μm using a rotary microtome.

(4) Stain sections with Carazzi's hematoxylin, or use the Jordet J-322 Dip-Quick Stains (Rossell and Sheehan 1998) as an alternative to Carazzi's hematoxylin.

One of us (YGW) originally colored the very tiny neonatal pituitary of rats with acid fuchsine for determining orientation of sagittal-sections of the pituitary, but did not describe this method in any journal. MH applied this method to the identification of white-colored phalanges in white-colored paraffin, as a more efficient method for skeletochronology (e.g., in 558 individuals of *Salamandrella keyserlingii* inhabiting Kushiro Marsh, Japan: M. Hasumi, unpubl. data). Acid fuchsine was soluble in water but insoluble in alcohol, and therefore it was retained through final dehydration and paraffin embedding, but washed out during subsequent procedures in which water was used, and thus did not hinder final staining of bone (Fig. 1B).

This procedure is a rapid and efficient method for accurate processing of large numbers of phalangeal samples. It provides visible bone that is easy to orient in paraffin, sections that adhere well to glass microscope slides, and a staining method that clearly distinguishes lines of arrested growth in bone.

Acknowledgments.—We express our gratitude for the constructive comments of Michael Grace and one anonymous reviewer.

The study of life history, growth and population dynamics is critical in the development of comprehensive management strategies for amphibian populations. Typical methods include capturing and marking individuals and studies of an individual's growth and movement. Traditional amphibian marking has been some combination of toe clipping. Toe clipping is a good way to mark individual specimens but many species can regenerate toes within one season (Ott and Scott 1999). Additionally, toe clips can sometimes be confounded by individuals who have lost toes to accident or predation. Tracking movements has been accomplished by use of radio telemetry, but this technique is costly and time consuming (French et al. 1992; Oldham and Swan 1992; Madison and Ferrand 1998' Werner 1991). Currently, there are few studies focused on expanding the use of Radio Frequency Identification (RFID) antennas to track individuals buried in the soil. There is no single method that accomplishes individual marking and individual tracking with efficiency and economy (Ferner 1979).

One alternative is the use of Passive Integrated Transponder (PIT) tags and PIT tag antennas to mark and track individuals. Use of PIT tags and Radio Frequency Identification (RFID) antennas allow positive identification of individual animals over the life of the individual (Brown 1997). Many studies have used PIT tags for the assessment of movement, growth and population parameters (Eggert 2002; Matthews 2003; Richter and Seigel 2002). The use of PIT tags has several advantages in long term studies: PIT tags have high rates of retention if implanted properly; they have a low rate of mortality due to implantation; they can be functional for 10 to 20 years (greater than the lifespan for many salamanders); and they positively identify individuals (Kuhnz 2000; Matthews 2003; Pyke 2005).

Kuhnz (2000b) used PIT tags and RFID technology to track legless lizards in loose sandy soils at short distances. Several pertinent findings were presented including the following:

1) RFID antennas can detect PIT tags through sand, duff covered sand and wet sand to a distance of 12.0 cm.

2) RFID antennas can help to detect organisms in heavy vegetative cover.

3) Organisms can be located at short distances without disturbance using RFID antennas.

Kuhnz reported a minimum and a maximum detection distance for the unique circumstances involving legless lizards.

Ambystomatid salamanders spend much of their existence in the terrestrial environment in shallow tunnels either developed by

rodents or excavated on their own (Smith 2003). Because of this fossorial lifestyle, information on non-breeding habitat use and migration is incomplete. We evaluated the application of RFID antennas and PIT tags for tracking ambystomatid salamanders in their burrows. We tested the hypothesis that different antennas (described in methods) would have different detection distances (DD) and would perform differently when individuals were located at different depths within the soil. This experiment mimicked what we might expect to see in implementing RFID use in the field.

Our study uses the methodology of Kuhnz (2000b) but differs in the following ways:

1) We studied detection distances for two types of RFID antenna utilizing implanted salamanders in an open air treatment (control) and at different depths buried in soil in a 40 gallon Rubbermaid container.

2) We report maximal DD for both antenna types and describe their detection range and percent effectiveness in all experimental conditions.

3) We determined if the RFID tracking technique would be applicable in denser soils, which might block the antenna's ability to pick up the tag more than loose sandy soil.

TABLE 1. ANOVA table of mean detection distances and arcsine transformed % effectiveness of experimental RFID antennas.

Mean detection distances				
Source	df	Mean Square	F	Sig.
Depth	4	1.438E-02	1.322	.277
Antenna	1	6.928E-03	.637	.429
Depth X Antenna	4	1.962E-02	1.804	.145
Error	44	1.087E-02		

Arcsine transformed % effectiveness				
Source	df	Mean Square	F	Sig.
Depth	4	15858.490	29.354	<.001
Antenna	1	2732.295	5.057	.028
Depth X Antenna	4	932.436	1.726	.156
Error	60	540.251		

Methods and Materials.—PIT tags were implanted in seven, laboratory-housed *Ambystoma tigrinum* salamanders according to protocols outlined by Ott and Scott (1999). These individuals are also validation specimens for an ongoing drift-fence study where salamanders are tagged in the field in a similar fashion.

Methods were modified from Kuhnz (2000b). Antennas tested in our study were the Destron 2001 F-ISO Circular antenna and the Biomark Triangular Field antenna using attenuation box antn-04. Antennas were supplied on loan for the experiment from Biomark, Inc. Both antennas tested are slightly different in design and application from the Avid Power Tracker II used by Kuhnz (2000). The Power Tracker II was designed as a handheld device with limited DD. The Biomark circular antenna is designed as a handheld but was designed with a greater DD. Additionally, the triangular antenna is reported to have a greater DD range and is designed for use with a handle at different distances. Our study was designed to determine the maximum DD in typical soil found in North Dakota. Soil used in the study was obtained from a local source and was classified as clay loam (NRCS, 2002).

To develop a comparable measure of antenna performance we use the term detection distance (DD), which is defined as the distance between the antenna and the PIT tag at which a read response (detection) is initiated. In this study DD was determined by progressively lowering the antennas from a height of 30 cm in a leveled, straight line above the specimen until the tag was identified or until the surface of the soil was reached. Two parameters were recorded: tag detection (positive or negative) and DD (in the case of a positive detection). For many of the trails the tag was detected well in advance of the antenna reaching the soil level. Thus a soil depth of 13.2 cm might have a DD greater than 13.2.

PIT implanted salamanders were placed in a cloth bag to limit movement and then covered with differing levels of soil. The DD was recorded for each trial with every salamander tested five times for each of the different antennas within each experimental condition. This allowed for a total of 175 tests of detection and DD per antenna (350 detection attempts).

Antennas were analyzed for detection and DD using differing levels of soil coverage as experimental conditions. The following amounts of soil were used as mimics of soil depth in field conditions; 0 cm, 2.2 cm, 6.6 cm, 13.2 cm, and 15.4 cm of loose soil. Data were log-transformed for DD, arcsine transformed for % effectiveness, and analyzed with separate two-factor ANOVAs. Factors were antenna type and depth of soil covering salamander. Additionally, to avoid pseudoreplication only the mean values of each salamander were used for running the ANOVAs. In all hypothesis tests, α was set at 0.05. Where appropriate, significant hypothesis tests were followed by post hoc analysis with the least significant difference (LSD) test.

Results.—No significant differences in DD were observed between antenna types, or among soil depth profiles (Table 1). However, significant differences were observed when the % effectiveness was analyzed (Table 1). The circular antenna read at a greater distance in all treatments except the treatment without soil (Table 2).

There was a progressive loss of effectiveness in both antennas at increases in soil depth beyond 6.6 cm, at 13.2 cm and 15.4 cm the circular antenna showed less of a loss in effectiveness than the triangular antenna (Table 2).

Both antennas recorded at least one detection in each of the experimental conditions. There was a maximal DD for each of the antennas in all treatments (Table 2). The loss in effectiveness for the triangular antenna at 15.4 cm was 10 times greater than the loss for the circular antenna (Table 2).

Discussion.—Our study results support the use of PIT tags and RFID antenna to track and locate ambystomatid salamanders in fossorial burrows and in the terrestrial and aquatic environment. Both antennas tested could locate pit tagged salamanders in the loosely packed soil used during the tests. Additionally, both antennas could detect tags that were implanted in salamanders in soil of at least 15.4 cm; this condition approximates real field conditions. Of importance to researchers is the fact that this range of

detection is well within the burrow resting depth profile (Smith 2003). It is also important to note here that adult *A. tigrinum* have been found to excavate their own burrows or to utilize small mammal burrows within the effective range of both of these antennas but may also be found at greater depths which would be outside of the range of the antennas tested (Semlitsch 1983). This may be of importance for the researcher attempting to use antennas to locate individuals; the antennas tested may be more effective at distance detection when the individuals are occupying resting sites closer to the surface such as during breeding or active foraging.

TABLE 2. Percent effectiveness (# of tag detections/number of detection attempts × 100) of antennas in experimental conditions, including Detection Distance Maximums (DDM) for each antenna. For each animal at each depth 5 detection attempts were made, N = 350 (total number of detection attempts).

Treatment	% Effectiveness Circular Antenna	DDM	% Effectiveness Triangular Antenna	DDM
0 cm	100%	21.5 cm	100%	22.5 cm
2.2 cm	100%	26.2 cm	100%	22.2 cm
6.6 cm	100%	25.8 cm	97.1%	24.8 cm
13.2 cm	74.3%	21.8 cm	37.5%	20.8 cm
15.4 cm	28.6%	22.8 cm	2.8%	19.8 cm

The DD for an antenna is influenced by many factors including but not limited to: position of the tag in the individual, chemical component of the medium between the tag and the antenna (air, water, and soil), additional obstacles between tag and antenna (i.e. rocks, metal, landfill debris, other field equipment, or somebody's leg) and the angular relationship between the antenna field and the tag. It was not within the practical scope of this study to test these additional variables yet these are all factors that have a great deal of influence on antenna performance.

The tests that were performed supported the hypothesis that RFID antennas can locate herpetological study specimens at some distance beneath the soil. It follows that this method may also be utilized to track paedomorphic ambystomatids in aquatic habitat if they are within the DD for the antenna.

Both of the antennas tested showed a considerable loss in tag reading performance when the individual was buried in 15.4 cm of soil (Table 2). Each antenna showed an optimal range of performance (between 8 and 18 cm) and a discernable limit to the DD in open air and in soil covered treatments (Table 2). Beyond 6.6 cm the circular antenna was more effective at reading tags (Table 2).

Overall, both antennas showed the ability to read pit tags implanted in salamanders in typical loose packed North Dakota soil at least 15.4 cm deep. From our experiments we have determined the effective detection range for these antennas in our experimental conditions to be anywhere from 8 to 22 cm. Both antennas detected pit tags right at the limit of their reported detection range (Biomark reports a 25.4 cm limit for these antennas).

The valuable discovery for the field herpetologist is that the circular antenna was much more effective compared to the triangular antenna. The current cost of the triangular antenna is three times the cost of the circular antenna (please consult with Biomark for current prices and additional considerations). This type of cost differential is a real consideration for the researcher juggling limited budgets.

As a result of our research, we will be incorporating several aspects of tracking and locating salamanders in the field while utilizing RFID antennas. We will be working on a protocol for randomized and transect oriented surveys for our tagged salamanders in the terrestrial and aquatic environment and we will continue to test some of the other variables affecting antenna effectiveness and DD. Multipurpose use of PIT tags and antennas will allow the herpetologist to optimize the value of the cost of using pit tags in research. Continued research into alternative uses for pit tags will assure that manufacturers incorporate added value in the future development of PIT tag hardware.

Acknowledgments.—We thank C. Ouedraogo, J. Richter, J. Tennyson, and H. Modrow for assistance. C. K. Beachy provided suggestions for improving the manuscript. This research was funded by NIH grant Number P20 RR016741 from the INBRE Program of the National Center for Research Resources. We also thank D. Sens and C. K. Beachy for continued support. We thank A. Hopkins and Biomark for their support of this research. Additionally, the comments of an anonymous reviewer greatly improved the clarity and content of this manuscript.

Use of Anesthesia Increases Precision of Snake Length Measurements

KIRK SETSER

e-mail: kwsetser@gmail.com

Researchers typically use body length (snout–vent length; SVL) as the principal measure of snake size. Several techniques for determining SVL have been reported (e.g., Blouin-Demers 2003; Fitch 1987; Quinn and Jones 1974). However, numerous researchers have also commented on the imprecision of common methods of measuring snake length (e.g., Blouin-Demers et al. 2002; Fitch 1987; Madsen and Shine 2001; Measey et al. 2003; Taylor et al. 2005). In at least one publication, SVL measurements were considered so imprecise that head length was considered a more consistent measure of snake size than SVL (Houston and Shine 1994). Despite recognition of this problem, until recently, little effort has been made to report the precision of different measurement methods, or to assess sources of variation. Recently, several researchers have quantified measurement error in SVL measurements. However, these studies stopped short of testing factors which influence measurement error (e.g., Bertram and Larsen 2004; Blouin-Demers 2003).

Variation between SVL measurements may be partitioned into three source categories: variation between measurements made by a single measurer using a single technique (e.g., the "intrinsic limitations" of a measuring method; Blouin-Demers 2003),variation between measurements made by different measurers using the same technique, and variation between measurements made using different techniques.

It is likely that the greatest source of variation in SVL measurement results from differences between measurements of stretched and unstretched snakes (Fitch 1987). I consider measurement of unstretched snakes preferable for numerous reasons. 1) snakes spend the majority of their lives in relaxed postures, thus measurement of an unstretched snake is a truer measure of snake length; 2) stretched measurements are positively biased in comparison to measurements of preserved snakes (Fitch 1987; Reed 2001) and indirect measurements (e.g., squeeze box measurements; Bertram and Larsen 2004); 3) large snakes may be difficult to completely stretch, resulting in decreased precision (Fitch 1987; but see Blouin-Demers 2003); 4) snakes may vary in elasticity as well as in behavioral resistance to stretching, biasing interspecies comparisons; 5) stretching venomous snakes poses a danger to measurers; and 6) stretching can injure snakes (Fitch 1949, 1987). For these reasons, I chose to only evaluate methods for measuring unstretched snakes.

Here, I present the results of two separate evaluations of SVL measurement precision. In the first part of this study, I evaluated sources of variation in repeated SVL measurements of a diverse group of snakes. My objective was to quantify the effect of each source of error in SVL measurement, as well as to identify the most precise measurement technique. In the second portion of this study, I quantified the precision, under research conditions, of the most precise of the previously evaluated techniques.

Materials and Methods.—In the first portion of this study, I evaluated repeated SVL measurements of 24 snakes using three snake measurement techniques: squeeze box (Quinn and Jones 1974), conscious-straightened, and anesthetized. To increase the breadth of the statistical population, snakes from seven species (*Charina bottae, Crotalus horridus, C. lepidus, Elaphe emoryi, Lampropeltis pyromelana, L. triangulum,* and *Heterodon nasicus*), four clades (Colubrinae, Crotalinae, Erycinae, and Xenodontinae), and comprising a range of sizes (210–957 mm SVL) were selected. Measurements were recorded based on the following design; two measurers measured each snake three times per technique, resulting in 18 measurements of each snake. All measurements were recorded during a single session. Most measurements were performed independently, and each measurer was unaware of values recorded by the other measurer. However, measurers helped one another restrain venomous snakes during conscious-straightened measurements, and thus may have been aware of the values of these measurements.

In the second portion of this study, I quantified the precision of measurements of 24 anesthetized adult *Crotalus polystictus* recorded under more typical research conditions (i.e., taken by different measurers over a longer time frame while measurers were primarily focused on tasks other than snake measurement). Each snake was measured once by three measurers, totaling three measurements per snake. Snakes were measured as they were captured over a nine-day period. Measurers were instructed on measurement technique the first day, but were not provided subsequent instruction. All measurements were taken independently. However, some measurers were aware of some previously recorded values, possibly influencing subsequent measurements.

During both portions of the study, measurers attempted to measure from the snout to the posterior tip of the anal plate of each snake. For measurements made with a squeeze box, the position of each snake's anal plate was marked on the snake's dorsum using a temporary marker prior to measurement.

To measure snakes with a squeeze-box, snakes were placed within a wooden squeeze box (61 cm × 61 cm) outfitted with a plexiglass lid and lined with a 5 cm thick foamed rubber pad. Snakes were pressed against the pad with enough force to temporarily retard movement while measurers traced the dorsal mid line of the snake from snout to the anal plate mark using a temporary

TABLE 1. Variance components of SVL measurements divided by measurement technique and measurer. Number of measurements recorded from each snake (m), mean SVL, mean within-subject standard deviation (s_w), coefficient of variation (CV), and percent measurement error (ME) of repeated measurements of live snakes. Two measurers ($measurer_1$ and $measurer_2$) each measured 24 snakes three times using each technique, thus N = 24 in all cases.

technique	m	mean SVL (mm)	s_w (mm)	CV	ME
$conscious_1$	3	527	11.2	2.1	0.25
$conscious_2$	3	544	5.7	1.1	0.06
$squeeze_1$	3	494	14.5	2.9	0.45
$squeeze_2$	3	505	12.5	2.5	0.31

total	18	524	24.7	4.7	1.16

marker. Measurers then draped a cotton cord along this line and measured the resulting length of cord along a flexible steel measuring tape. Snakes were allowed to move freely within the squeeze-box between measurements.

To measure snakes using the straightened-conscious technique, snakes were laid alongside a flexible steel measuring tape placed atop a table. Because substantial measurement variation can occur due the degree a snake is stretched, measurers attempted to straighten each snake without stretching it. Larger, more powerful, snakes that could not be straightened without stretching were measured piecemeal, with consecutive portions of the body straightened along the measuring tape. Venomous snakes were measured while an assistant restrained the head and 2-5 cm of the body inside a tightly fitting plastic tube while the measurer straightened the remainder of the body along the tape. Snakes were allowed to rest and re-coil briefly between measurements.

To measure snakes using the anesthesia method, snakes were anesthetized to the point that they lost all muscular rigidity using isoflurane gas (Blouin-Demers 2003; Blouin-Demers et al. 2000). Although the goal was to measure completely relaxed snakes, some snakes regained slight muscular control and rigidity before all measurements were recorded. Each snake was placed on its side and gently straightened along a flexible steel measuring tape resting atop a table. To avoid stretching, snakes were straightened by running a thumb or other finger along the ventral scales of the snake while simultaneously applying slight pressure to the corresponding portion of the snake's dorsum. Snakes were manually coiled then restraightened between measurements.

Snakes were anesthetized within plastic snakes tubes. I administered isoflurane using a variation on Blouin-Demers et al.'s open method (2000). Administered dosages ranged between 1.44 ml/l and 1.62 ml/l (1 and 2 ml of isoflurane in 0.70 and 1.24 l tubes). Isoflurane was injected into a cotton ball placed at the bottom of a glass vial, then topped with a second, dry, cotton ball and placed in the tube with each snake. Tubes were closed with rubber stoppers, but were not airtight. Because evaporation of isoflurane was slowed by the cotton and by the glass vial, and because tubes were not airtight, the dose of isoflurane delivered was undoubtedly lower than the administered dose. Time until complete muscle relaxation varied greatly among species. In general, crotaline snakes reached anesthesia rapidly, while colubrine snakes took longer.

I calculated variance components of the dataset from the first part of this study using a one-way ANOVA with SVL as the dependent variable and individual snakes as the independent variable (Bland and Altman 1996). Variance was partitioned into among-subject (s^2_A) and within-subject (s^2_W) components (Bailey and Byrnes 1990). I calculated measurement errors (ME), a relative metric describing the percentage of variation attributable to measurement error, and coefficients of variation (CV), a relative metric describing the within-subject standard deviation (s_W) as a percentage of the mean SVL.

To explicitly evaluate the contribution of measurement technique, measurer, and snake clade on measurement precision I evaluated variation between standard deviations of the measurements of each snake with a mixed-model ANOVA with individual snake as a random effect and measurement technique, measurer, and snake clade as fixed effects. Interactions between technique and measurer and technique and clade were included in the model. Snake length was not included as a factor because values of standard deviations can be expected to correlate with values of SVL; however snake size may influence the relative precision of SVL measurements (Blouin-Demers 2003).

To quantify the precision of measurements recorded in the second portion of this study, I partitioned variance components of these data with a one-way ANOVA and calculated ME and CV to describe measurement precision.

All statistical tests were performed with SAS 9.1 (SAS Institute Inc. 2004).

Results.—Measurements of snakes taken using the squeeze-box method were the least precise, while those taken under anesthesia were the most precise (Table 1). Precision decreased when measurements from two observers were combined, irrespective of measurement technique. Precision was poorest when measurements from different techniques and measurers were combined (Table 1). Measurements recorded using the squeeze-box technique were negatively biased in comparison with measurements recorded using anesthetized and conscious-straightened techniques, which shared similar mean values (Table 1).

Measurement precision was most strongly impacted by measurement technique (Table 2). One measurer was consistently more precise than the other measurer (Table 1), resulting in a measurer effect (Table 2). Neither clade, nor any interactions, contributed to measurement precision (Table 2).

Measurements of anesthetized snakes under research conditions were highly precise, despite measurements being taken by multiple measurers (mean SVL = 589 mm; s_w = 1.7 mm; CV = 0.3%; ME = 0.05%). The most disparate measurements of any individual snake were 586, 591, and 595 mm, a span of 9 mm. All three measurements of two snakes agreed exactly. The mean span between a snake's three measurements was 2.6 mm.

Discussion.—The most important source of variation in precision was measurement technique. A smaller effect on precision was due to differences between measurers. Although measurements recorded by each measurer using a single technique were rela-

TABLE 2. Results from a mixed model ANOVA of standard deviations (mm) from 3 SVL measurements per snake per technique per measurer of 24 live snakes. Individual snakes were treated as a random effect, and sources were treated as fixed effects.

source	numerator df	denominator df	F	P
technique (t)	2	109	16.32	< 0.0001
measurer (m)	1	109	5.14	0.025
clade	3	20	0.96	0.433
t x m	2	109	0.61	0.545
t x clade	6	109	1.19	0.315

tively precise, precision diminished when measurements taken by different measurers using different techniques were combined. Precision can be optimized by relying on a single measurer using a single technique. For this reason, caution should be exercised when combining data taken by different measurers using different techniques. This is particularly true when some techniques may exhibit not only substantial measurement error, but also bias (e.g., measurements of stretched snakes and measurements taken using squeeze boxes; Bertram and Larsen 2004; Blouin-Demers 2003; Fitch 1987; this study). Particular care should be exercised with measurements collected using a squeeze box. Bertram and Larsen (2004) reported a substantial negative bias of squeeze box measurements in comparison to measurements of stretched snakes. Results from this study indicate a similar bias exists even when snakes are not stretched.

Surprisingly, neither clade nor the clade by method interaction influenced measurement precision. Measurers subjectively considered muscular, constricting snakes such as *Elaphe* and *Lampropeltis* more difficult to control, and hence to measure. However, this difficulty did not produce less precise measurements. Similarly, Blouin-Demers (2003) had hypothesized that measurements of conscious large *Elaphe obsoleta* would be less precise than measurements of small conspecifics due to the difficulty of controlling larger snakes, but demonstrated an opposite effect.

Additional testing of measurements of anesthetized snakes taken under more typical research conditions indicated that multiple measurers can record highly precise measurements when provided with brief instructions on measurement technique. Imprecision (expressed as CV) was less than one percent of the mean body size of adult *C. polystictus*, a level of imprecision unlikely to impact conclusions of most studies.

Based on the results of this study, I advocate that snakes be measured while anesthetized when this option is feasible. In addition to high precision, measurements of unstretched, anesthetized snakes can be assumed to be less likely to display a bias in comparisons with measurements of preserved snakes than measurements taken using other techniques (based on Reed 2001; Fitch 1987). Use of anesthesia also eliminates the need to forcefully handle snakes, reducing the likelihood of injuries to snakes and the risk of bites from venomous snakes. Finally, increased standardization of measurement technique would facilitate comparisons among studies.

Use of anesthesia has four principal drawbacks. Foremost is the potential for snake death (Blouin-Demers et al. 2000). In studies involving sensitive taxa and/or small populations, the precision of measurements necessary to achieve research goals should be carefully balanced against potential mortality. Second, use of anesthesia is time consuming and may be impractical in studies where large numbers of snakes need be measured quickly. Third, although isoflurane has been widely used in mammals, the effects of isoflurane on snakes are less studied. Therefore, currently unreported deleterious side effects may exist. Side effects may be more likely with repeated exposure to anesthesia, such as may occur in growth studies. Finally, the use of anesthesia adds to research costs (ca. US $13 for 100 ml of isoflurane).

Acknowledgments.—I thank M. Amarello and G. U. Lozano-de la Rosa for assistance in measuring snakes. I thank M. Goode for use of equipment. I thank M. Ingrasci, J. Meik, E. Mociño-Deloya, B. Setser, C. Setser, and D. Setser for comments on earlier versions of this paper. Data were collected in accordance with research permit G1212 issued to D. Lazcano by SEMARNAT.

Un-Weathered (New) Artificial Cover Objects Effectively Sample Plethodontid Salamanders in Michigan

TERESA A. (YODER) CARLSON
and
ERNEST J. SZUCH
Biology Department, University of Michigan-Flint
Flint, Michigan 48502, USA
e-mail (TAC): teresay@umflint.edu
e-mail (EJS): szuch@tds.net

Many plethodontid species are small salamanders with restricted home ranges and are sensitive to natural and human disturbances, making them potential indicators of environmental health and biodiversity (Caro and O'Doherty 1999; Welsh and Droege 2001). Since the 1990s, many studies have documented population declines in amphibians, including salamanders, stressing the need for appropriate population monitoring techniques (Blaustein and Dobson 2006; Blaustein et al. 1994; Kohler et al. 2005; Pechmann et al. 1991; Pounds et al. 2006; Young et al. 2004). One such method for monitoring terrestrial salamander populations is the use of Artificial Cover Objects (ACOs).

ACOs cause little disturbance to the environment and require less time, effort and maintenance compared with other monitoring techniques. The repeatability of studies using ACOs and the ability to standardize this technique using number and area of cover objects also makes this method useful (Grant et al. 1992). The Terrestrial Salamander Monitoring Program (TSMP), established in the mid 1990s, recommends ACOs for monitoring terrestrial salamander populations (Droege 1997). Several studies have attempted to determine the most appropriate way to set up ACOs; however, very few ACO investigations have been done in the Midwestern United States and some specifics of the method are still debated in the literature (Bonin and Bachand 1997; Carfioli et al. 2000; Davis 1997; DeGraaf and Yamasaki 1992; Hyde and Simons 2001; Marsh and Goicochea 2003; Monti et al. 2000; Moore 2005). The TSMP protocol suggests that boards should be placed on bare, leveled soil and weathered for a year before any data are collected (Droege 1997). However, this protocol delays data collection, a potential problem in necessarily short-term surveys. To alleviate this problem, Bonin and Bachand (1997) suggested placing boards on existing wet leaf litter to accelerate the weathering process and reduce the time needed before data can be collected.

The goals of our study were 1) to investigate effectiveness of ACOs to sample terrestrial salamanders in Michigan, 2) to investigate use of aged boards versus new boards and 3) to provide baseline data for *Desmognathus fuscus*, a newly documented species in Michigan (Carlson and Szuch 2005).

In 2004, we set up ACOs at Kresge Environmental Education Center (KEEC) at Fish Lake in Lapeer County, Michigan. KEEC is owned by Eastern Michigan University and consists of 240 acres surrounded mostly by state land. The property consists of one large lake, several small lakes, a tamarack bog, mixed hardwood forests and many kettle ponds. We set up ACOs around a kettle pond surrounded by mostly deciduous forest to determine if there was a preference for aged boards placed on bare, leveled soil or new boards placed on existing wet leaf litter. ACOs consisted of CDX pine plywood (1.9 cm thick) cut to 121.9 × 61.0 cm. Size and design of boards were determined during a preliminary study in 2003 that tested four ACO designs of Carfioli et al. (2000). Aged boards were weathered for a year while new boards were weathered for only two weeks. All boards were placed in the field at the same time to eliminate bias. New boards were placed directly on existing leaf litter with no modification to the ground. Aged boards were placed on the ground after it had been cleared of leaf litter and leveled. Twenty-three pairs of boards were placed equidistantly around the pond approximately 10–12 m apart. Each pair consisted of one aged board and one new board. Within each pair, one board was placed near the pond's edge and the other board was placed 6–8 m upslope from the pond's edge. The location of board type relative to the pond, near or far, was alternated around the pond. ACOs were held in place with aluminum tent stakes and left in the field for two weeks before collecting data. Boards were checked biweekly from 28 April to 12 November 2004. Salamanders found beneath boards were identified to species, measured (SVL) and released at edge of boards.

During the 2004 field season, we observed 154 salamanders: 130 *Plethodon cinereus*, 17 *Ambystoma laterale*, 4 *Notophthalmus viridescens*, and 3 *Ambystoma maculatum*. Only data for *P. cinereus* were further analyzed. Without regard to season, *P. cinereus* were encountered under aged boards placed on bare, leveled soil significantly more than under new boards placed on existing topography and leaf litter (χ^2 = 20.320, df = 1, $p < 0.05$; Fig. 1). *P. cinereus* were encountered under boards that were upslope or farther from the pond's edge significantly more compared to boards that were down slope or closer to the pond's edge (χ^2 = 15.820, df = 1, $p < 0.05$); however, no association was found between number of encounters and age and location of board (χ^2 = 3.380, df = 1, $p > 0.05$).

Salamanders were most active in spring (28 April – 8 June 2004) and fall (3 September – 29 October 2004), with fall being the season of greatest activity (Fig. 1). In spring there was no significant difference in use of board type (χ^2 = 0.267, df = 1, $p > 0.05$) and in fall, aged boards placed on bare, leveled soil were used more than new boards placed on existing topography and leaf litter (χ^2 = 21.943, df = 1, $p < 0.05$). Boards that were placed upslope or farther from the pond's edge were used more in both spring and fall seasons (spring, χ^2 = 6.667, df = 1, $p < 0.05$; fall, χ^2 = 7.467, df = 1, $p < 0.05$). That *P. cinereus* were encountered more frequently under boards placed upslope or away from the pond's edge is not surprising since it has no aquatic larval stage and is not dependent on vernal or permanent ponds for breeding. *Plethodon cinereus* is often found farther from water than other terrestrial salamanders and avoids areas prone to flooding (Harding 1997; Petranka 1998).

That *P. cinereus* preferred aged boards placed on bare, leveled soil to new boards placed on existing topography and leaf litter corroborates TSMP recommendations; however, if age was the primary factor affecting board use, we would expect little or no use of new boards and significantly more use of aged boards in spring. We would also expect a more equitable use of aged and new boards in fall when both board types would be weathered. Our results suggest just the opposite. There is equal use of aged

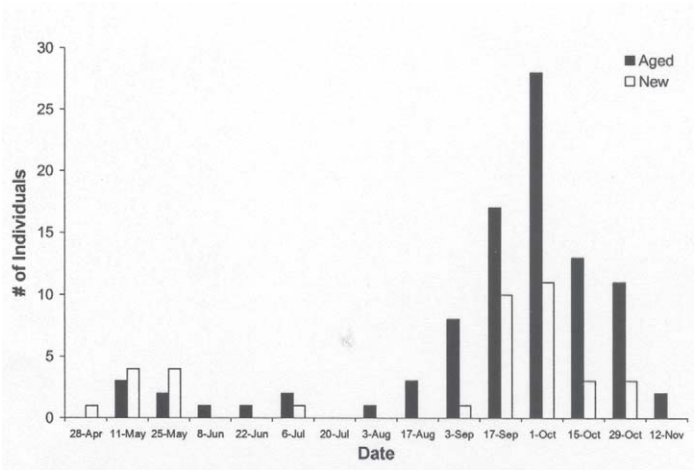

FIG. 1. Number of *Plethodon cinereus* observed beneath aged (weathered) boards placed on bare, leveled soil and new (un-weathered) boards placed on existing topography and leaf litter at Kresge Environmental Education Center, Lapeer County, Michigan in 2004.

and new boards in spring and a preference for aged boards in fall. This led us to speculate that something other than age was determining board use. In spring when conditions are typically cool and humid, both board types may offer suitable conditions for salamanders; however, in fall when conditions are typically warmer and drier, boards placed on bare, leveled soil may create a cooler, more humid micro-environment compared to new boards placed on unleveled ground with existing leaf litter.

In 2006, we tested our hypothesis that there was no significant difference in use of aged or new boards when both were placed on bare, leveled soil. Because of the recently discovered population of *Desmognathus fuscus* in Michigan (Carlson and Szuch 2005), we changed our research location to Murphy Lake State Game Area (MLSGA) in Tuscola County, Michigan. MLSGA is composed of 2645 acres surrounded mostly by agricultural land. Our study site was located in a Hemlock-Northern Hardwoods Forest

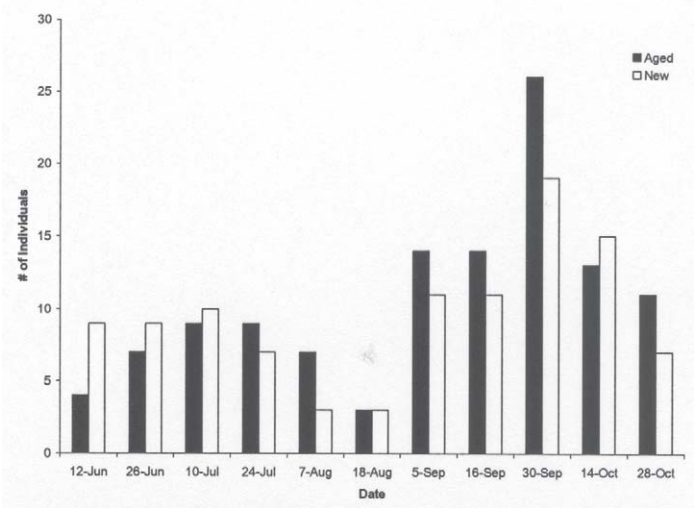

FIG. 2. Number of *Plethodon cinereus* observed beneath aged (weathered) and new (un-weathered) boards placed on bare, leveled soil at Murphy Lake State Game Area, Tuscola County, Michigan in 2006.

(Barnes and Wagner 2004) near the northern boundary of the game area. CDX pine plywood (1.9 cm thick) was cut to 30.5 × 61.0 cm. Smaller ACOs were used to better resemble downed woody debris. Boards were placed in pairs containing one aged board and one new board approximately 15 cm apart and each pair of boards was placed approximately 6 m apart. Aged boards were weathered for 2–3 years and new boards were weathered for only two weeks. All boards were placed in the field at the same time to eliminate bias. The site for each board was cleared of leaf litter and leveled before placing the board on the ground. Aluminum tent stakes were used to keep boards in place.

Within the forest community, three adjacent terrestrial sub-habitats were studied: 1) edge of a kettle pond, 2) within the forest proper and 3) along a stream. Thirty pairs of boards were used to sample the three sub-habitats with 10 sites in each sub-habitat. At the pond, half of the sites were placed 2 m from the pond's edge and the other half were placed directly along the pond's edge. In the forest proper, half of the sites were placed along a ridge, while the other half were placed either upslope or down slope relative to the ridge. Along the stream, each pair of boards was placed flush with the edge of the stream bank. Boards were checked biweekly from 12 June to 28 October 2006. Salamanders found beneath boards were identified to species, measured (SVL) and released at edge of boards.

During the 2006 field season, we observed 352 salamanders: 221 *Plethodon cinereus*, 116 *Desmognathus fuscus*, 6 *Hemidactylium scutatum*, 6 *Ambystomaa maculatum*, and 3 *A. laterale*. Only data for *P. cinereus* and *D. fuscus* were further analyzed. *P. cinereus* was found in all three sub-habitats: 81 individuals at the pond, 125 individuals in the forest proper and only 15 individuals along the stream. *D. fuscus* was only found along the stream.

Considering all three sub-habitats, we found no significant difference in number of encounters of *P. cinereus* between aged or new boards ($\chi^2 = 0.652$, df = 1, $p > 0.05$, Fig. 2). We also failed to detect a significant difference in encounters between aged or new boards in the pond, forest or stream sub-habitats (pond, $\chi^2 = 0.049$, df = 1, $p > 0.05$; forest, $\chi^2 = 1.512$, df = 1, $p > 0.05$; stream, $\chi^2 = 0.000$, df = 1, $p > 0.05$). There was also no difference in mean SVL of *P. cinereus* found under aged or new boards (Mean SVL $_{new} = 35.516 \pm 0.695$ mm, Mean SVL $_{aged} = 37.182 \pm 0.552$ mm, t = 1.973, df = 184, $p > 0.05$).

For *D. fuscus*, we detected no significant difference between encounters under aged boards versus new boards ($\chi^2 = 1.043$, df = 1, $p > 0.05$, Fig. 3); however, mean SVL of individuals found beneath aged boards was greater than mean SVL of individuals found beneath new boards (Mean SVL $_{new} = 31.196 \pm 1.453$ mm, Mean SVL $_{aged} = 35.403 \pm 1.305$ mm, t = 1.983, df = 103, $p < 0.05$). No gilled larvae were observed beneath boards, but juveniles as small as 14.7 mm SVL and adults as large as 55.9 mm SVL were observed (Fig. 4).

ACOs are an effective sampling technique for monitoring some species of terrestrial salamanders in Michigan. Six species were found beneath boards during both field seasons; however, only two species were found in quantities large enough for statistical analysis. Ambystomatid salamanders are terrestrial as juveniles and adults but often spend the majority of their lives underground. This behavior may explain why ambystomatids were found in low

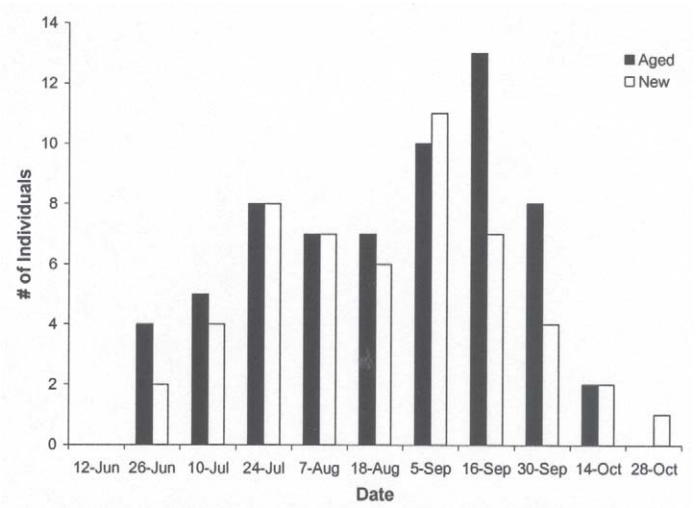

Fig. 3. Number of *Desmognathus fuscus* observed beneath aged (weathered) and new (un-weathered) boards placed on bare, leveled soil at Murphy Lake State Game Area, Tuscola County, Michigan in 2006.

numbers in our study as well as in studies by Bonin and Bachand (1997) and Grant et al. (1992). *Notophthalmus viridescens* is primarily terrestrial as a juvenile (eft) and often disperses away from its natal pond during this life-history stage.

The other three species found beneath boards are all terrestrial salamanders that we would expect to find in large numbers beneath ACOs. For two of these species, *P. cinereus* and *D. fuscus*, that was the case in our study. This corroborates findings of Stewart and Bellis (1970) and Carfioli et al. (2000). We are unsure why *H. scutatum* was found in low numbers but speculate that it is either because they have low population sizes at our study sites or that microhabitat conditions beneath boards were not ideal for this species.

Finding large numbers of *P. cinereus* during both the 2004 and 2006 field seasons was not surprising considering how common this species is throughout the Midwest. It can reach densities as high as 500-9000 per hectare in some parts of its range (Harding 1997; Heatwole 1962). *Desmognathus fuscus* was not documented

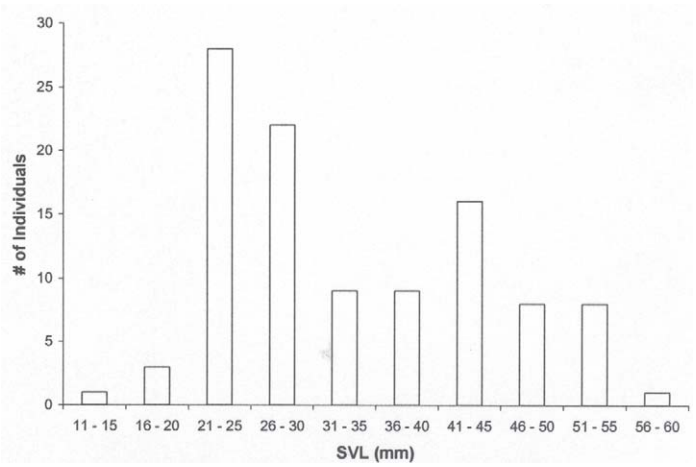

Fig. 4. Number of *Desmognathus fuscus* observed in SVL categories at Murphy Lake State Game Area, Tuscola County, Michigan in 2006.

in the state of Michigan until fall 2004 (Carlson and Szuch 2005). An unpublished study by Carlson and Szuch demonstrated that *D. fuscus* in Michigan could be sampled with ACOs placed either in the stream channel or on the stream bank, but not on boards placed 2 m from the stream. Finding such large numbers of *D. fuscus* at MLSGA suggests that the population is well-established and the range of SVLs observed suggests that reproduction is occurring.

In 2006, we tested the hypothesis that age of boards was not the factor affecting board use by terrestrial salamanders and found that when aged and new boards were both placed on bare, leveled soil, there was no difference in encounters between board types. This was observed in both *P. cinereus* and *D. fuscus*. Additionally, we found no difference in mean SVL for *P. cinereus* beneath aged or new boards; however, mean SVL of *D. fuscus* was larger under aged boards. These results suggest that the need to weather boards may be dependent on location, species and goals of the investigation. We found that in Michigan weathering boards is not always needed if the goals of the study are to determine species presence/absence and estimates of abundance; however, if the goal is to determine population age structure, boards may need to be weathered or a variety of board types may need to be used. For *P. cinereus*, weathering does not appear to be needed for studies in Michigan; however, in the case of *D. fuscus*, weathering boards may allow larger individuals to be sampled. Overall, we found that monitoring terrestrial salamander populations with ACOs in Michigan works well for *P. cinereus* and *D. fuscus*; however, further studies may find ACOs useful for other species.

Acknowledgments.—We thank two anonymous reviewers for helpful comments on an earlier version of this manuscript. We thank Melissa Borowiak, Tiffany Fender, Acacia White, and students from the 2006 Field Biology and Topics in Ecology Courses at UM-Flint for their assistance in the field. Larry Atherton helped in attaining equipment and supplies. Permission to conduct research at KEEC was granted by Ben Czinski and Eastern Michigan University and at MLSGA by Arnold Karr of the Cass City Office of the Michigan DNR. Funding for this project was provided by the Murchie Memorial Research Fund and Biology Department of UM-Flint. Teresa Carlson was supported (in part) by a Graduate Student Research Assistantship from the Office of Research and Office of Graduate Programs at UM-Flint. This study complied with all applicable state of Michigan land use and scientific collection permits issued by the Michigan DNR and research was conducted under animal use protocol 09427 issued by the University Committee on the Use and Care of Animals of the University of Michigan.

Wildlife populations world-wide are threatened by habitat loss associated with human activities. One such activity is the extraction of rock for use in building and landscaping (Webb and Shine 2000). Quarrying practices may include the use of explosives and heavy machinery, both of which can cause mortality in wildlife. The problem is further exacerbated for nocturnal rock-dwelling reptiles because they may be difficult to detect, capture or translocate due to the inaccessibility of the habitat, complications of working at night, and/or a lack of effective capture methods. Although some authors have questioned the merits of translocation (e.g., Dodd and Siegel 1991; Reinert 1991), it may be the only means of preventing certain deaths in resident wildlife at sites where approval for rock extraction has been granted.

Here, I compared the sampling effectiveness of two methods for capturing terrestrial geckos (*Hoplodactylus maculatus*) from a basalt rock outcrop in New Zealand. *Hoplodactylus maculatus* is a primarily nocturnal species that uses postural adjustments to thermoregulate by day within retreat sites (Rock et al. 2002). Although *H. maculatus* is considered to be a cryptic species complex (Daugherty et al. 1994), I have used the term *H. maculatus* here pending formal description of the members of the species complex. The 'Canterbury' form encountered in this study is regarded as a distinct and threatened species by the New Zealand Department of Conservation (DOC; Hitchmough et al. 2007).

The basalt was nominated for extraction by NZ Quarry Managers Ltd., prompting capture and translocation of geckos in the year preceding rock extraction in accordance with conditions stipulated by DOC (Bruce Arnold, Department of Conservation, Christchurch, New Zealand, pers. comm.). The two capture methods used were searches of natural cover and artificial retreats (i.e., artificial cover objects or coverboards). Other methods could not be used because the steep, rocky terrain did not allow for the use of pitfall traps, and locating and capturing emerged animals at night by spotlight (Whitaker 1967) was considered too risky.

Artificial retreats have previously been used to sample a range of herpetofauna, including terrestrial salamanders (DeGraaf and Yamasaki 1992; Monti et al. 2000), frogs (Pearman et al. 1995; Wakelin et al. 2003), snakes (Hoyer and Stewart 2000; Kjoss and Litvaitis 2001; Reading 1997), and lizards (Lettink 2007; Lettink and Cree 2007; Sutton et al. 1999). More recently, artificial retreats were used in attempts to restore degraded habitats (Michael et al. 2004; Webb and Shine 2000) and to increase the abundance of endangered Pygmy Blue-tongue Lizards (*Tiliqua adelaidensis*; Souter et al. 2004). Although the technique itself is not new, the

retreat design used here is a recent and original development (Lettink 2007; Lettink and Cree 2007).

Measures of sampling 'effectiveness' considered in this study were catch-per-unit-effort (i.e., number of geckos captured per person h) and the proportion of animals that evaded capture (i.e., escapes). In addition, adult sex ratios and size (snout-vent length) distributions of geckos captured by each method were compared to assess whether artificial retreats and searches of natural cover produced similar samples.

Materials and Methods.—The study site was located on a basalt rock outcrop in the Kaituna Valley, South Island, New Zealand (173°41'E, 43°46'S; Fig. 1). A 2500 m^2 area on the lower slopes of this outcrop was nominated for quarrying due to the quality and accessibility of the rock contained within (Greg Wright, NZ Quarry Managers Ltd., Christchurch, New Zealand, pers. comm.). This 2500 m^2 area (hereafter referred to as the study site) was flanked by exotic forest (a *Pinus radiata* plantation), introduced woody weeds (primarily gorse *Ulex europaeus*) and grazed pasture. Also present were native lianas (*Muehlenbeckia complexa*), divaricating shrubs (a growth habit characterized by extreme branching; *Coprosma* spp., *Melicope simplex*, *Melicytus alpinus*) and several small tree species (*Griselinea littoralis*, *Kunzea ericoidis*, *Macropiper excelsum*). The study site had a slope that varied from ca. 30°–70° with an east/northeast aspect and an elevation of 60–100 m above sea level.

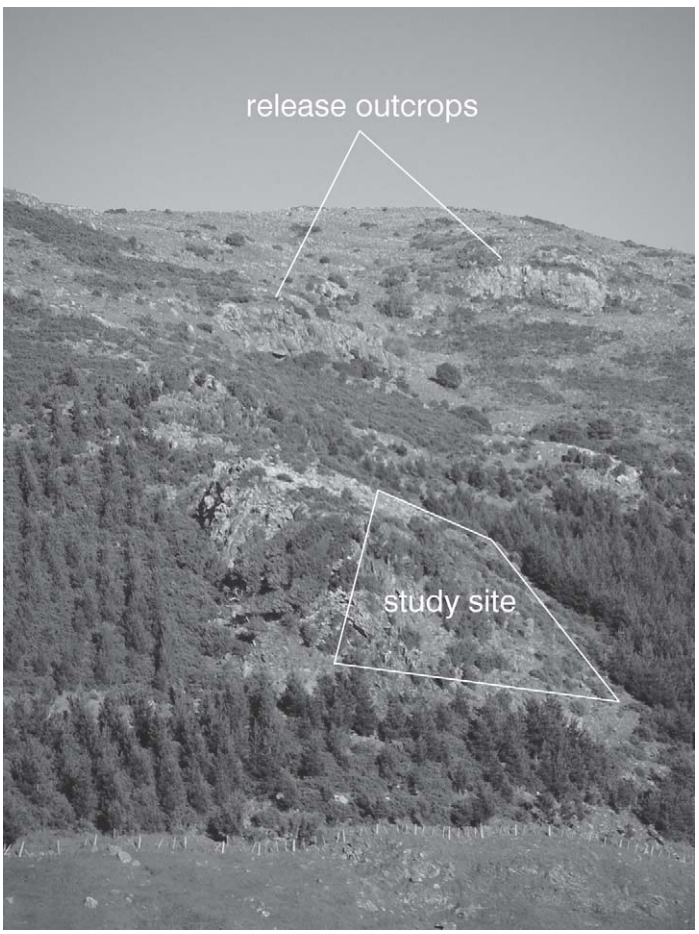

FIG. 1. Study area in the Kaituna Valley, South Island, New Zealand. Geckos (*Hoplodactylus maculatus*) were captured from the study site and released at two nearby rock outcrops.

FIG. 2. A double-layered artificial retreat made of Onduline positioned among basalt rocks and vines to attract the nocturnal gecko *Hoplodactylus maculatus*, Kaituna Valley, South Island, New Zealand. Animals are captured by hand when each layer is sequentially overturned.

In November 2005, 20 artificial retreats were installed within the study site. The artificial retreats were made of Onduline, a lightweight corrugated roofing and cladding product made from organic fibres saturated with bitumen (Composite Insulation Ltd., Christchurch, New Zealand; available world-wide http://www.onduline.com). Previous research revealed that *H. maculatus* preferred artificial retreats made of Onduline over those made of corrugated iron and concrete (Lettink and Cree 2007). In addition, Onduline retreats were shown to be highly effective at detecting *H. maculatus* following translocation when compared to pitfall traps (Lettink 2007).

Onduline retreats consisted of two 400 mm x 280 mm sheets stacked on top of each other (Lettink and Patrick 2006) and oriented horizontally or on a slight incline (up to ca. 30°). Sheets were separated by short (~2 cm) lengths of 10 mm-diameter pine dowel glued beneath the corners and centre of each sheet, and weighed down with one or two small rocks (Fig. 2). Approximate costs for materials were US $2 per artificial retreat. Placement of retreats was non-random to maximize the number of gecko captures. Most artificial retreats were placed near rock jumbles with deep crevices containing gecko faeces. Where possible, retreats were also positioned near patches of the liana *M. complexa*, favored by lizards for the shelter, invertebrate prey and fleshy fruits it provides (Whitaker 1987).

The study area was visited by up to three observers on seven occasions in 2006 (4 April, 6 April, 7 April, 20 May, 24 October, 29 October and 3 November) following a 'settling in' period of five months. All observers had previously worked with lizards. Some artificial retreats were re-positioned within the study area on 24 May to increase coverage. Capture sessions typically commenced at 0900 h (or earlier) on mornings when shade air temperatures were 15°C to facilitate easy capture and minimize the risk of escapes. Geckos were captured by hand by sequentially overturning each layer of a retreat and were placed in cotton holding bags. Geckos were sexed and measured after all artificial re-

TABLE 1. Number of geckos (*Hoplodactylus maculatus*) captured from Onduline artificial retreats and searches of natural cover, Kaituna Valley, New Zealand, April–November 2006. N = number, CPUE = catch-per-unit-effort (number of geckos captured per person h). Natural cover was not searched on the first and last occasions.

	Artificial Retreats				Natural Cover Searches			
Occasion	N seen	N caught	Person hours	CPUE	N seen	N caught	Person hours	CPU
1	18	15	2.5	6	—	—	—	—
2	17	13	2	6.5	12	6	4	1.5
3	4	4	1	4	6	2	7.5	0.27
4	26	25	2	12.5	6	3	2	1.5
5	16	16	2	8	1	1	0.5	2
6	9	9	1	9	3	2	1	2
7	5	5	1	5	—	—	—	—
Total	95	87	11.5		28	14	15	

treats had been checked. Mature males were identified by the presence of a hemipenial bulge and spurs. Animals of equivalent size lacking male reproductive structures were assumed to be females and subjected to gentle palpation of the abdominal region to determine whether follicles and/or embryos were present. Snout-vent length was measured to the nearest mm using a clear plastic ruler.

Natural cover was searched (by rock turning and crevice inspections) on all except the first and last sampling occasions. Most of the surface rock could not be turned because slabs were too heavy or deeply embedded in the ground. Geckos sighted within crevices were gently guided to a position where they could be captured by the observer(s), using flexible insulated electrical wire or pieces of vegetation. All geckos captured were sexed and measured as described above. The catch-per-unit-effort (i.e., number of geckos captured per person h) was noted for both methods and included the time taken to record measurements.

Captured geckos were released at two rock outcrops approximately 180 m (N = 69) and 470 m (N = 32) west of the quarry (Fig. 1). Additional Onduline retreats and rocks were used to create habitat at a number of release sites along the base of these outcrops. It was not known whether geckos would attempt to home back to the quarry site; however, I hoped that the poor quality of the intervening habitat (grazed pasture with patches of gorse) and additional habitat created at release sites would reduce the likelihood of such events occurring. Previous research revealed that *H. maculatus* was capable of homing over short distances (110 m; Marshall 1983) but failed to do so when moved over a distance of 1 km (Lettink 2007). Release sites were re-visited on an opportunistic basis and checked for the presence of *H. maculatus*.

Program R was used for all statistical analyses (R Development Core Team 2004). A Wilcoxon rank sum test (Crawley 2005) was used to compare the mean catch-per-unit-effort (CPUE) between methods. Pearson's chi-square tests were used to compare the number of escapes, adult sex ratios and size-class distributions between methods. For the latter, geckos were assigned to three groups (SVL 41 mm, 42–55 mm, and 56 mm) that corresponded approximately to neonates, juveniles and adults (Lettink Unpubl. data). Yates' continuity correction and simulated P values (N = 2000 replications) were used for 2 × 2 and 2 × 3 tables, respectively, because some of the categories contained fewer than 5 counts (Sokal and Rohlf 1995, Venables and Ripley 2002). A significance level of 0.05 was specified for all statistical tests.

Results.—After seven occasions, 101 geckos were captured, with artificial retreats producing the majority of captures (91.6%; Table 1). Mean CPUE for artificial retreats was 7.3 ± 1.08 SE (range 4.0–12.5), which was higher than CPUE for searches of natural cover (mean = 1.5 ± 0.32 SE, range = 0.3–2.0; W = 30.5, P = 0.042). Twenty-two animals escaped during capture sessions with significantly fewer escapes from artificial retreats than searches of natural cover (χ^2 = 22.7, df = 1, P = < 0.001; Table 1).

Snout-vent lengths of geckos captured (N = 101) ranged from 30–75 mm (mean = 54.5 ± 1.39 SE; Table 2). The smallest geckos for which sex identification was possible had SVLs of 56 mm. All animals with SVLs 56 mm were therefore considered adults. Adult male:female ratios for searches of natural cover (4:8) and artificial retreats (23:21) were not significantly different between

TABLE 2. Size-class distributions of geckos (*Hoplodactylus maculatus*) caught from Onduline artificial retreats and searches of natural cover, Kaituna Valley, New Zealand, 2006. N = number of geckos, SVL = snout–vent length, SE = standard error. Differences in size-class distributions between methods were significant (χ^2 = 6.96, P = 0.02).

Method	N	Neonates (SVL 41 mm)	Juveniles (SVL 42–55 mm)	Adults (SVL 56 mm)	SVL range (mm)	SVL Mean ± SE (mm)
Artificial retreats	87	25	18	44	30–75	53.1 ± 1.54

methods (χ^2 = 0.70, df = 1, P = 0.40). Differences in the observed size-class distributions between methods were significant (χ^2 = 6.96, df = 2, P = 0.02), probably due to poor representation of neonates (N = 0) and juveniles (N = 2) from searches of natural cover (Table 2). The size-class distributions of samples from both capture methods were dominated by adults.

Opportunistic checks of artificial retreats installed at release sites resulted in sightings of 0 to 16 geckos per retreat. The group of 16 geckos was observed on 24 October , approximately five months after the last release at that site. This suggests that at least some geckos remained at the retreats where they were released; however, as individuals were not marked, translocated geckos could not be distinguished from any resident geckos that may have been present.

Discussion.—Onduline artificial retreats were superior to natural cover searches in the measures of sampling effectiveness considered in this study. More than 90% of the geckos captured were from artificial retreats. Moreover, CPUE was five times that observed for searches of natural cover, and fewer animals escaped from artificial retreats. In addition, the size range of animals captured from artificial retreats was much greater. The technique can be considered highly effective for capturing *H. maculatus* from rocky habitats that are difficult to sample by other means. It would be of great interest to know how many animals remained at the site, but unfortunately this could not be ascertained. The comparison of sampling methods therefore remains relative, and findings should not be generalized to other sites or habitats.

Onduline artificial retreats are likely to be useful in other reptile translocations, providing both an effective capture method and refuges where these are lacking. Future research should focus on defining the time period required for maximal occupancy of artificial retreats, as this will determine both the total number of animals that can be captured during a removal operation and the optimal time-frame required. Determining whether translocations of *H. maculatus*—an extremely long-lived species with a low recruitment rate—are ultimately successful may require a commitment spanning multiple decades (Lettink 2007). Additional research into the behavior of translocated reptiles is also needed. Whether translocation is an appropriate tool to allay conflicts between commercial activities and natural habitats for threatened species remains a key issue that merits further consideration.

Acknowledgments.—Research was conducted in accordance with a Low Impact Collection and Research Application Permit #CA–134856 FAU from the New Zealand Department of Conservation. I wish to thank B. Popup Archival Transmitting (PAT) tags are a relatively new tool used in marine animal studies (e.g., Block et al. 1998; Prince and Goodyear 2006; Sims et al. 2005). These tags differ from conventional satellite tags in that they collect and archive temperature, depth, and light level (for geolocation estimates) data over a period of time and then automatically are released from the animal on a designated date and transmit data to ARGOS satellites; the tag must detach before the data are transmitted. PAT tags are often used in survival studies (Domeier et al. 2003; Horodysky and Graves 2005).

One of the most important components of the system is the tether and how it is attached to the animal to ensure that the tag stays on and does not affect the behavior of the animals. Additionally, attachment is a compromise between the need for the tag to be released properly from the animal and the need for a long-term attachment which would still allow for a break-away link should the animal become entangled in fishing gear, marine debris, etc. Because the animals do not need to surface with the tag so that the satellite receives the data—instead the tag is released, floats to the surface, and transmits the archived data—the tether can be quite short, which reduces the risk of entanglement.

Marine turtles are protected species that interact with numerous types of fishing gear throughout the world (Gerosa and Casale 1999; Henwood and Stuntz 1987; Julian and Beeson 1998), often with lethal consequences. Pelagic longlines are identified as a source of mortality for marine turtles (Kotas et al. 2004; McCracken 2000; Yeung 2001), although the majority of the animals are released alive (Watson et al. 2005; see references above). However, the impacts of the fisheries have yet to be quantified because the post-hooking mortality rates are not known. NOAA Fisheries initiated a project in 2001 to evaluate the feasibility of using PAT tags to determine the post-hooking survival rates of marine turtles interacting with the pelagic longline fishery in the North Atlantic (Epperly et al. 2002; Sasso and Epperly 2007). Herein, we describe the tether system and attachment of PAT tags to Loggerhead Turtles, *Caretta caretta*, used in the pilot study. We monitored the attachment of PAT tags on three captive-reared loggerhead sea turtles in order to (i) evaluate the impact of the attachment on the turtles and (ii) determine if the attachment could remain intact for a one year deployment, the duration we needed to evaluate annual survival rates at sea.

Test Animals.—In May 2003 non-functional, but otherwise intact PAT tags (Wildlife Computers, Inc., Redmond, Washington, USA) were attached to three captive reared Loggerhead Sea Turtles in the NOAA Fisheries Service Laboratory in Galveston, Texas, USA (Fig. 1). The 31 month-old animals hatched from nests adjacent to Clearwater, Florida, USA in 2000. After emergence from the nest, the hatchlings were transferred to the Galveston rearing facility. Husbandry of turtles at this facility is described in Higgins (2003). The animals ranged in size from 48.1 to 49.8 cm minimum straight carapace length (SCL) at the time of tag attachment. In early June, soon after PAT tags were attached, one turtle (RRA816) was transferred to the NOAA Fisheries Service Laboratory in Panama City, Florida, USA where it was placed in a large outdoor pen (14.2 m long × 7 m wide × 0.9–1.5 m deep, depending on the tide) in St. Andrew Bay, with 12 or fewer other individuals of the same age. The other two turtles remained in Galveston. The one turtle was moved to better simulate conditions in the wild. The large outdoor pen allowed the turtle to swim more and faster and to dive deeper, exposed the animal to wave action and to UV radiation, and allowed for interaction with structures and with other animals. While in Panama City the turtle was fed a diet of squid (*Illex illecebrosus*). The Panama City turtle was returned to Galveston in early July. While in Galveston, the turtles were fed a minimal growth diet of whole Atlantic Mackerel (*Scomber scombrus*) in order to simulate the growth rates of wild turtles of that size (~5 cm yr^{-1}) (Mendonça 1981; NOAA Fisheries Service, unpubl. data; Schmid 1995). The turtles were held in-

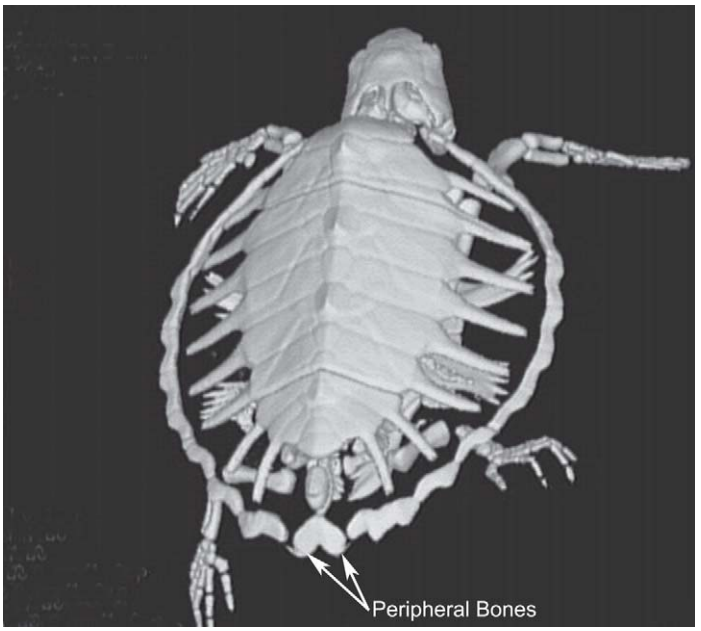

FIG. 2. Computed tomography (CT) scan of an immature loggerhead turtle showing peripheral bones which underlie postcentral scutes.

doors in a large divided raceway where each was allocated a space of 2 m × 1.8 m with a water depth of 0.9 m.

PAT Tag Attachment.—In order to attach PAT tags, the animals were removed from their raceway and immobilized on a platform of clean wet foam placed in a shallow plastic crate. Throughout the process, all attempts were made to maintain as aseptic a working environment as possible. Latex surgical gloves were worn throughout and changed frequently to avoid contamination. The caudal surfaces of the plastron and carapace were cleaned and any barnacles were removed. The area was scrubbed using sterile gauze sponges and 10% povidone iodine solution at least three times over a 15 min period, and the area was maintained damp with the solution. The posterior carapacial scutes were iced for 15 min to numb the area to be drilled. All attachment hardware and the drill bit were soaked in 10% povidone iodine solution for 15 min before they came in contact with the turtle. A 4.8 mm titanium nitride coated steel drill bit was used and drill speed was low to minimize frictional heat. Although there was no bleeding, a drop of Clotisol® (Benepet® Pet Care Products, St. Joseph, Missouri, USA; ferric sulfate, aluminum sulfate, collagen protein, and chloroxylenol in suspension) was placed in each hole prophylactically, and then the hole was flushed with 10% povidone iodine solution.

An eye strap connected to the carapace was used as an anchor for attaching the PAT tag (Fig. 1). The attachment involved drilling a pair of holes through the postcentral scutes and their peripheral bones, from dorsal to ventral (Fig. 2 and Fig. 3). The centers of the holes corresponded to centers of the attachment holes in the eyestrap. A 3.8 cm × 1.1 cm 18-8 stainless steel (SS) standard line eye strap was attached to the turtle with 2 SS slotted, round head bolts (#10/24 × 2.4–5.1 cm) and a #10/24 SS locking nut with nylon insert. The bolts were inserted ventral to dorsal when the length of the bolt was long enough to extend well past the locking nut and potentially chafe the rear flippers. In contrast, a dorsal to ventral insertion was used when the bolt was appropriately sized such that it did not extend well past the locking nut. Nylon washers (6.4 mm outside diameter) were placed between the SS hardware and the turtle (Fig. 3). Nylon washers were used rather than SS washers because nylon is both inert and flexible, allowing for fit to a scute's irregular surface, and it does not have any sharp edges. The locking nuts were threaded over exposed bolt ends and tightened until there was no space between the pieces of attachment hardware.

PAT Tag Tether.—A 10 cm long tether was used to connect the PAT tag to the eye strap. One end of the monofilament (182 kg test fluorocarbon, 1.8 mm diameter) was looped around the plastic thimble attached to a corrodible pin in the tag, and crimped using SS sleeves (oval, for 1.6 mm wire rope). The other end was looped around a 2 mm SS thimble for monofilament line and crimped. The thimble was attached to the eye strap before the bolts were

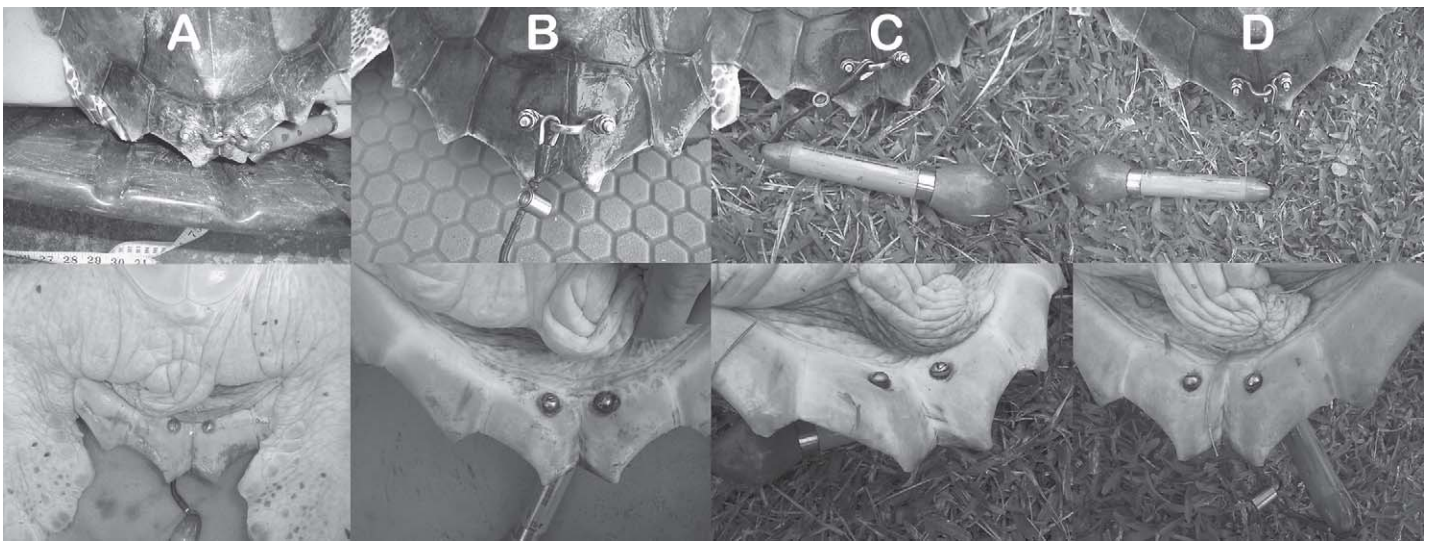

FIG. 3. Dorsal and ventral views of the PAT tag attachment on a 2000 year class loggerhead sea turtle (*Caretta caretta*; RRA806) photographed throughout the year: (A) May 22, 2003, (B) July 24, 2003, (C) November 17, 2003, and (D) May 20, 2004. The eye strap is bolted through the postcentral scutes and the underlying peripheral bones.

threaded through the shell. In order to prevent the tag from being crushed under extreme pressure (usually associated with great depths), the tether was equipped with a device (RD-1500) that severs the monofilament releasing the tag when a depth (approximately 1500 m) well outside the normal diving range of sea turtles is reached. The RD-1500 was centered on the tether. Marine grade adhesive-lined heat shrink tubing (3.2 mm and 4.8 mm inner diameter for line and crimp sleeves, respectively) was applied over the monofilament and both crimp sleeves on either side of the RD-1500 to reduce the monofilament's exposure to ultraviolet radiation and to prevent abrasion of the line. A corrodible pin base of the PAT tag provided a breakaway safety link for the turtle (22.7 kg static weight breaking strength) in case of unanticipated entanglement.

Monitoring.—During the following 12 months, the turtles were monitored for changes to the attachment (e.g., loosening bolts, corrosion), the tether (e.g., chafing, breakage), and impact to the turtle (e.g., necrosis, entanglement). The turtles were removed weekly from the raceways and both the dorsal and ventral surfaces of the attachment were photographed (Fig. 3). All authors monitored the fine resolution digital photographs (1024 × 768 pixels).

Computed Tomography Imagery.—The tags were removed in May 2004 and the animals, now 51.4–56.0 cm SCL (13.4–22.2 kg), were examined using Computed Tomography (CT) imaging (Wyneken 2005) to evaluate the impact of the attachment on the underlying bone (Fig. 4). Turtle health and body condition were normal. Prior to CT imaging, the animals were fasted for more than 48 hours. After removing the hardware, the animals were anesthetized using ketamine (5 - 6 mg/kg IV), medetomidine (0.15–0.18 mg/kg IV), and reversed with atipamezole (0.7–0.9 mg/kg IM) (after Chittick et al. 2002). The animals were sedated in 2–3 min and lightly anesthetized in 4–9 min. Animals were reversed 18–26 minutes after their initial injections, and recovered to a mildly sedated condition in 17–18 min. While sedated, the animals' heart rates were monitored using an ultrasonic doppler flow detector with an 8.9 MHz probe (Model 811-BTS, Parks Medical Electronics, Inc., Aloha, Oregon).

Results and Discussion.—Previous attachment methods for conventional satellite tags on cheloniid turtles relied on epoxy glued bases and/or fiberglass (Balazs et al. 1996; Godley et al. 2002; Swimmer et al. 2006). However, because of the turnover in scute material, these attachment systems may be sloughed before the tracking time is complete. Conventional tags required placement high on the carapace or at the end of a long tether to allow for transmission when a turtle surfaces. The PAT tag does not transmit while attached to the study animal. Thus, we were not restricted to placement high on the carapace, where drag is highest (Watson and Granger 1998), and could use a short tether. We elected to use a through-bolted attachment, relying on a pair of holes, rather than a single hole, to distribute torque from the tether over two attachment points and increase the chance of maintaining attachment integrity. The postcentral scutes were selected because: (i) the rear aspect of animals with tapered body profiles is a region of low drag (after Bannasch et al. 1994; Watson and Granger 1998); (ii) the postcentral scutes are supported by a pair of articulated peripheral bones that provide a strong, accessible and easily located attachment site (Fig. 2) (see Wyneken 2001), and (iii) given a sufficiently short tether length, both it and the tag would be out of the way of the rear flippers and the turtle's visual field. Holes were drilled proximally on the postcentral scutes, but clear of the ventral skin, to ensure that both bone and keratin supported the bolts. If holes are drilled distally in the scutes, they might only pass through the keratin, a weaker support than the composite we chose.

We used two criteria in the design of the tether. First, we wanted the tether to be long enough for tag to reside within the turbulent wake of the turtle, minimizing or effectively eliminating hydrodynamic costs to locomotion. Thus, the tether had enough length (10 cm) to allow the tag to follow behind the turtle and somewhat above the posterior-most part of the carapace. Secondly, the tether was also short enough so that the tag trailed linearly and avoided entangling or bumping the hind limbs when the turtles were swimming or in rough surface waters. The construction of our tether for sea turtles was modeled on the tether used in research of pelagic fishes (Graves et al. 2002; Prince and Goodyear 2006).

No general anesthesia or local anesthetic was administered during attachment. There are no conclusive studies of pain control in turtles or applicable studies in other reptiles to override the need to avoid risks from general anesthesia or injectable mammalian analgesics (Schumacher and Yelen 2005; Wyneken et al. 2005). In order to simulate anticipated field conditions in which the PAT tags would be attached and deployed on wild animals, we used ice as a potential local analgesic and avoided anesthetics. Trained fisheries observers would be attaching the tags to turtles caught at sea, often days to a week from the nearest port and away from veterinary support. Additionally, turtles would be released immediately following PAT tag attachment so post-anesthesia monitoring would not be possible. Furthermore, research permits would not allow for the administration of general anesthesia by the observers. Local anesthetic injection was not feasible as the attachment site was hard keratin overlying bony carapace. Innervation to the shell is via spinal nerves and their extent within bones is unknown. While we made attempts to minimize discomfort (15 min focal ice application, slow drill speed), some turtles initially reacted to the drilling by pushing with their limbs against the foam and crate, attempting to propel themselves forward, and were briefly (< 1 min) restrained. Based on videos of the animals taken immediately after they were placed in their holding tanks and taken the day after attachment, there was no overt evidence of continued discomfort subsequent to the attachment procedure, and weight gain over the next year was within the range for turtles without PAT tag attachment (NOAA Fisheries Service, unpubl. data).

The attachments remained intact for the full year (22 May 2003–25 May 2004) (Fig. 3), but the only grossly visible responses occurred within the first month. Within a week of attachment there was evidence of localized pressure necrosis deep to the washer on the ventral surface. The initial necrosis either progressed slightly or the holes wore over the next several weeks so that at the end of the first month the holes had enlarged a small amount allowing the eye straps to rock slightly (maximum ~1.5 mm) along the turtle's anterior-posterior axis and the bolts could move vertically (1–3 mm); these changes did not progress further. The nuts held fast and never loosened. The greatest eye strap movement was observed in the one turtle that was moved temporarily to a large outdoor pen in Panama City, Florida where it could swim greater distances and interact with other turtles as well as with the pen's

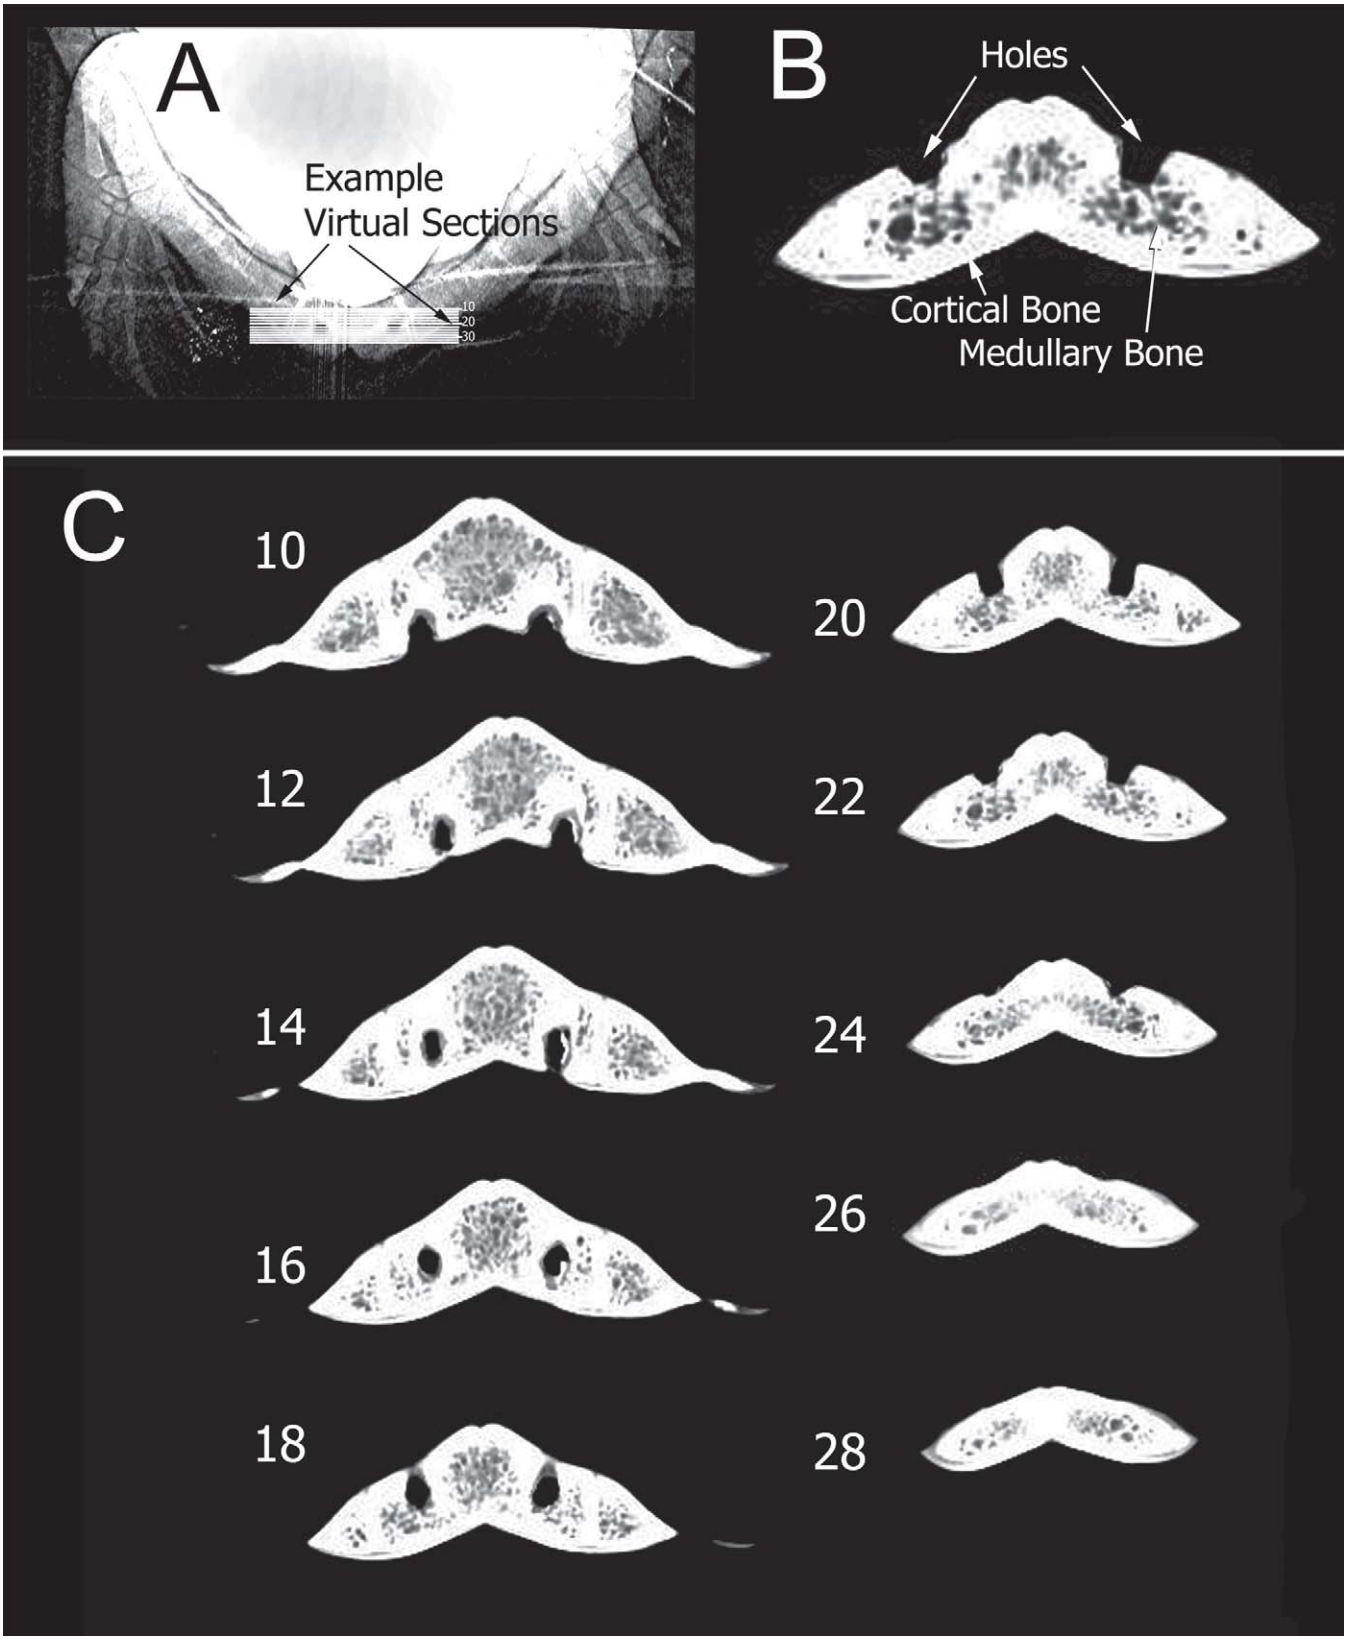

FIG. 4. (A) Computed tomography (CT) scans of the attachment site are collected as virtual serial sections (RRA806). (B) Cortical bone appears white; medullary (woven) bone appears gray. (C) Shown are the serial CT images of the posterior peripheral bones. Section 10 is the most anterior and section 28 the most posterior. The plane of sampling did not pass directly through the axis of PAT tag's mounting holes so they are shown starting with the inferior side of the holes and extending along the holes until just posterior to their superior openings. The bone along the holes is mostly compact, except along the tunnel walls where the stainless bolts passed (Images 12 right side, 14 right, 16-18). This gray material may represent adjacent debris or loosely woven bone. We could not distinguish the two without a biopsy; no biopsy was taken.

wall of webbing. During the first month all three turtles developed some microbial growth between the keratin and bone on the ventral surface around the holes. Over time, this resolved without treatment. Interestingly, it was least on the turtle that spent a month in Panama City where it was exposed to unfiltered sunlight.

After removing the tags, we found some cellular and keratinous debris in the bolt holes of two of the turtles, most of which fell out when the bolts were removed. Small depressions were present on the ventral surface around each hole, approximately the diameter of the washer. CT imaging showed the two bolt holes in the caudal-most shell region with little to no evidence of bone remodeling (Fig. 4C). None of the holes invaded into the coelomic cavity or caudal skin. There was no evidence of lysis surrounding the bolt holes and their borders had smooth margins; there was no evidence of clinically significant reaction.

The corrodible pins in the base of the tags were intact. The pin serves two purposes: (i) it is the weak link in the system and will break under enough stress, and (ii) it secures the tether to the tag and corrodes when the PAT-controlled application positively charges the pin to release the tag, which then will float to the surface. Temperature and salinity affect the rate of corrosion, but typically the pin breaks within 3 h, and is completely corroded within 9 h (Melinda Braun, Wildlife Computers, pers. comm.). Once the tag is free of the turtle, the turtle will still carry the tether and attachment hardware. Because the bolts were not marine grade stainless (e.g., they were 304 not 316 stainless), we fully expected the bolts to corrode and the hardware to be shed at some point well after PAT tag detachment on wild animals. There was some evidence of corrosion of the bolts, washers, and eyestrap when the hardware was removed after 1 yr.

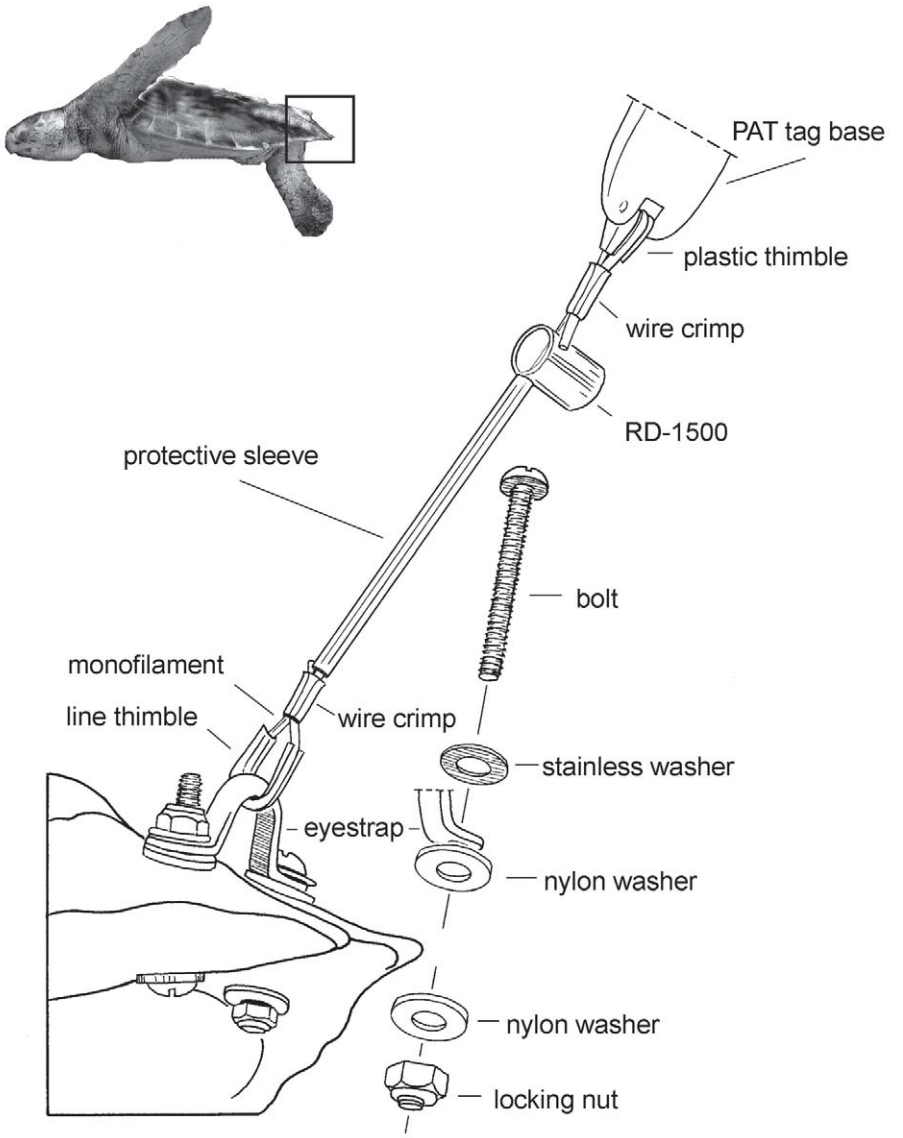

FIG. 5. Schematic of the current attachment hardware and tether for a PAT tag on a loggerhead sea turtle carapace (*Caretta caretta*). The corrodible breakaway pin in the base of the tag is not visible, but is surrounded by the plastic thimble. Note that the monofilament tail extending from the wire crimp sleeve is overlapping the RD-1500 to prevent it from spinning on the monofilament.

At the end of the study, the turtles were released in St. Joe Bay, Florida (29°49.5'N × 85°24.0'W) on 26 June 2004. They each bore 3 inconel flipper tags (one on the right front flipper and one on each rear flipper) and two 125 kHz passive integrated transponders (PIT tags; one in the right triceps superficialis muscle complex and one in the left front flipper, just above the second proximal scale on the trailing edge). Here we alert readers of the desire for follow-up information on the turtles, should anyone recapture the three test animals. We request readers to photograph the PAT tag attachment area (dorsal and ventral) and to contact us after the animal is released. Flipper tag numbers are RRA816/RRA801/RRA927 (PITs # 4367531D3B, 4349566D75), RRA806/RRA928/RRA929 (PITs # 43396C7F78, 4330691B6E), and RRA814/RRA930/RRA931 (PITs 4349504D1D, 43496A2344).

Since the conclusion of this laboratory study and after reviewing preliminary results from field testing, we made a few modifications to the tether and attachment to minimize the impact to the turtles and to ensure long deployments (Fig. 5). Wildlife Computers now recommends that the RD-1500 be placed adjacent to the corrodible pin in the tag and that a small length of the monofilament tether be left exposed through the crimp sleeve on the tether, overlapping the RD-1500 to prevent it from spinning around the monofilament which could score and weaken the line. Additionally, we learned that the application of heat weakens monofilament and no longer use heat shrink tubing. Instead, we now protect the monofilament with a flexible translucent sleeve (1.85 mm internal diameter). We found a variety of monofilament lines of the same diameter (1.8 mm), ranging in strength from 136 kg-test

to 182 kg-test, and we use them interchangeably. As a direct result of this laboratory research we now are using larger diameter (13 mm O.D.) nylon washers placed adjacent to the plastron and the carapace, and a 12 mm #10 stainless washer between the eye strap and the head of the bolt or the lock nut. Lastly, we are ensuring that the nuts are not over-tightened to minimize pressure necrosis.

We conclude that this procedure can be used in the field to attach PAT tags to wild cheloniid turtles of all species (with the possible exception of *Natator depressus*) without detrimental effect on the turtle, and that the attachment would be useful for long term tag deployments. Using the described methodology, NOAA Fisheries Service has released PAT tags on pelagic oceanic loggerheads captured in the north central North Atlantic Ocean. Of the 19 tags programmed for long deployments and that transmitted, only 4 released prior to 6 months (Sasso and Epperly 2007); we do not believe their premature release was due to attachment or tether failure.

Acknowledgments.—We thank the staff at the NOAA Fisheries Service Galveston Facility, particularly S. Kethan, for maintaining and photographing these large animals for a full year. We also are very grateful to Dr. B. Poteet and staff at Gulf Coast Veterinary Diagnostic Imaging and Oncology for the CT scans and radiology reports and to J. Javech and L. Stokes for assistance with figures. Lastly, we thank our numerous colleagues who discussed (and practiced) attachments with us and constructed tethers: A. Bolten, L. Belskis, M. Lutcavage, S. Morreale, E. Prince, A. Rhodin, C. Sasso, W. Witzell, and the late B. Riewald. This research was conducted under the authority of U.S. Fish and Wildlife Service (USFWS) Endangered Species Act Section 10 Scientific Research Permit #TE676379 and Florida Fish and Wildlife Conservation Commission (FWC) Marine Turtle Permits #015 and #030. Animals were held in compliance with USFWS, FWC, and Animal Welfare Act guidelines for captive animal care. The National Marine Fisheries Service (NMFS) does not approve, recommend, or endorse any proprietary product or material mentioned in this article.

The ability to recognize individual animals is valuable for estimating survival of individuals, population sizes, recapture rates, reproduction, and behavior of individuals through time (Gavin and Haas 1989; White et al. 1982). However, methods to uniquely mark salamanders are more problematic than for many other taxa because their small size, their permeable skin, and their ability to regenerate toes and skin complicates the use of traditional marking techniques.

Amphibians have been uniquely identified with coded wire tags, toe clipping (Clarke 1972), tattooing (Perret and Joly 2002), freeze-branding (Beebee 1996), beaded elastic waistbands (Beebee 1996; Gavin and Haas 1989), radioisotope tagging, photo-recognition of unique characteristics (Bailey 2004; Gill 1978), passive integrative transponders (PIT) (Perret and Joly 2002), alphanumeric tags (Buchan et al. 2005; Gower et al. 2006) and visible implant elastomer (VIE) (Bailey 2004; Marold 2001; Nauwelaerts et al. 2000) (marking reviews by Beebee 1996; Gavin and Haas 1989; Murray and Fuller 2000). These available marking techniques have limitations, many of which violate assumptions of mark-recapture studies. Most mark-recapture models assume that marks are not lost through time, read incorrectly, or likely to influence survival and behavior (Pollock 1991; Pollock et al. 1990), but these assumptions rarely are tested. For example, external tags may interfere with movement, behavior, or body condition of amphibians (Murray and Fuller 2000). Toe clipping is a commonly used and inexpensive method to mark amphibians; however, salamanders can regenerate toes (Heatwole 1961) and this method may decrease survival (Clarke 1972; Davis and Ovaska 2001; McCarthy and Parris 2004; Parris and McCarthy 2001). Individual recognition, sometimes in conjunction with photo-recognition of color patterns, is a useful, non-invasive method for identifying individuals of many salamander species (Bailey 2004), but not all species have clearly quantifiable or easily distinguishable markings. Amphibian color patterns may change with time (Arntzen and Teunis 1993), and identification may depend on photographic quality or software.

Visible implant elastomer (VIE, Northwest Marine Technology Inc., Shaw Island, Washington, USA) is an alternative to tagging or toe clipping and can be used in species too small for a PIT tag. This relatively new marking method involves subcutaneously injecting a liquid polymer into an animal to create individual patterns of colors by body location. Visible implant elastomer involves a longer period of handling than many traditional marking methods (Davis and Ovaska 2001), which may be more stressful to the animal and limit the number of individuals that can be marked in the field. Previous work has examined the influence of VIE on survival (Bailey 2004; Davis and Ovaska 2001; Harvey 2003; Marold 2001), body condition, (Bailey 2004; Davis and Ovaska), and the stress response of salamanders (Kinkead et al. 2006) in addition to evaluating tag loss (Davis and Ovaska 2001; Marold 2001) and observer bias (Bailey 2004). In these studies, survivorship following VIE marking was high, and tag loss and observer bias were low.

Despite the growing body of literature suggesting that VIE may be an appropriate marking technique, little information is available to guide researchers who plan to identify salamanders with VIE in choosing marking locations or colors of elastomer. Few researchers have quantified retention of marks for > 5 months (but see Davis and Ovaska 2001) and to our knowledge no experiments have compared effectiveness of different colors of VIE or marking locations on salamanders. Additionally, laboratory studies conducted on terrestrial life stages of salamanders have housed individuals in unnatural conditions, such as containers without soil or leaf litter (Bailey 2004; Davis and Ovaska 2001; Marold 2001), which may have affected mark retention.

Our objective was to evaluate VIE as an effective marking technique for Eastern Red-backed Salamanders (*Plethodon cinereus*), a widely studied salamander with relatively dark coloration. We investigated the effects of mark placement (dorsal or ventral marking) and color of VIE marks (red, blue, orange, yellow) on retention and visibility of marks for >1 year post-marking in a replicated laboratory experiment that mimicked natural habitat conditions.

Methods.—We collected Eastern Red-backed Salamanders on 31 March 2006 and housed them in a laboratory at Virginia Tech, Blacksburg, Virginia, USA, through 20 April 2007. We hand-captured 30 adult salamanders [snout–vent length (SVL) > 34 mm] (Petranka 1998) in the Jefferson National Forest, Montgomery County, Virginia. When capturing salamanders, we avoided gravid females. We transported salamanders to the laboratory, confirmed their reproductive condition and sex by candling with a fiber optic light (Gillette and Peterson 2001), weighed and measured (SVL) them. Salamanders were numbered one to thirty and randomly assigned to three treatments: dorsally marked (N = 12; 7 males, 5 females), ventrally marked (N = 12; 7 males, 5 females), or controls (N = 6; 3 males, 3 females).

We housed salamanders individually in plastic terrariums (approximately 50 × 30 × 20 cm) with a 15 × 15 × 5 cm wooden block for cover, approximately 6 cm of soil, and a 5-10 cm layer of deciduous leaf litter to simulate their natural habitat. Terrariums were kept on shelves in a temperature-controlled room with a 12:12 light-dark cycle. We changed leaf litter in the terrariums every 1–

3 weeks and misted leaves with water 1–2 times per week to allow the salamanders to behave naturally and forage for invertebrates in moist leaf litter. We prevented a shelf effect by randomly interspersing individuals in each treatment among the shelves.

At the beginning of the experiment, terrariums were enclosed with a plastic lid to prevent escape of study animals; however, several salamanders escaped so we secured the lids with rubber bands around terrariums, but losses continued. We minimized further escapes by sealing fiberglass screen to the terrarium rim with silicone caulking and then securing the lid on top to minimize moisture loss. Across the entire study period, 2 control, 5 ventrally marked, and 5 dorsally marked salamanders escaped. Escaped salamanders were replaced until 7 July 2006, after which 4 additional salamanders escaped. When salamanders escaped and were replaced with newly marked individuals, we evaluated their elastomer marks from their reset "time zero" (i.e., time of their replacement). Hence, sample sizes were smaller for later time periods.

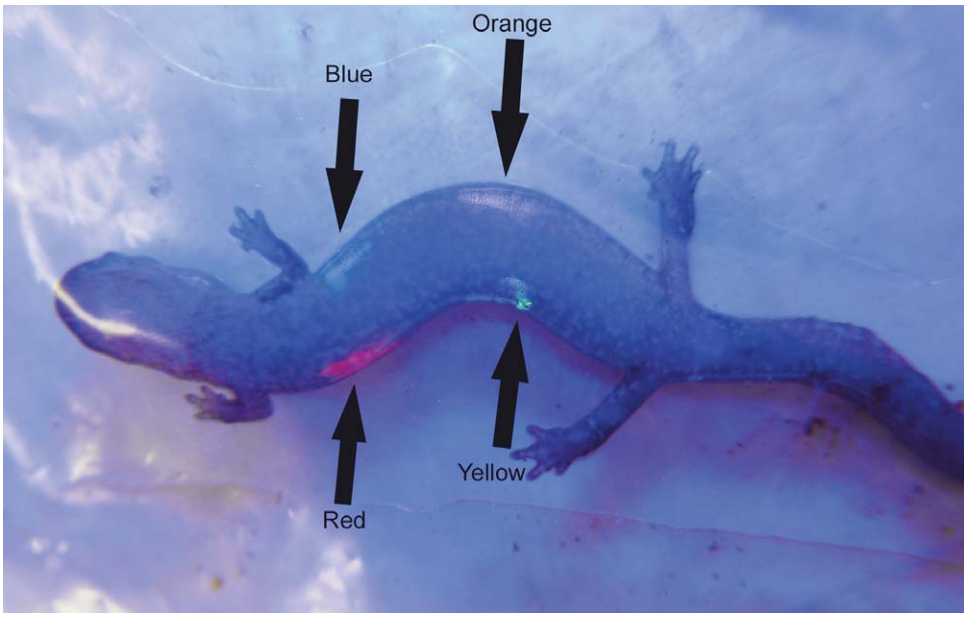

FIG. 1. Eastern Red-backed Salamanders (*Plethodon cinereus*) were marked with Visible Implant Elastomer in four locations, either ventrally or dorsally. Under fluorescent light, the appearance of some colors are altered.

One researcher (JAH) implanted all VIE marks subcutaneously with consistent placement of colors among salamanders for dorsal and ventral treatments. Red was placed posterior from the anterior left leg, blue was placed posterior from the anterior right leg, orange was placed anterior from the posterior right leg, and yellow was placed anterior from the posterior left leg (Fig. 1). Control salamanders (N = 6) were not marked nor treated with blank-injections and were used to qualitatively evaluate effects of VIE and associated handling on survival and mass. Marks were placed approximately 1–2 mm from the hip joint to prevent impairment of mobility, although exact placement varied because of the size of marks. Salamanders were placed in plastic bags to immobilize them and the elastomer was injected through the bag and into the salamander with a 1 cc insulin syringe.

Each week we weighed the salamanders and assessed elastomer marks with a visible implant (VI) fluorescent light (Northwest Marine Technology, Shaw Island, Washington, United States). VIE marks were evaluated on a 1–4 scale based on their difficulty to read, where 4 indicated "easily read," or could be seen under the VI light with no manipulation of the salamander body; 3 indicated "moderately easily read," or could be seen with the VI light with little manipulation; 2 indicated "difficult to read," or the mark could only be seen with a VI light after being manipulated for several seconds; and 1 indicated the mark was "absent," or not visible. We monitored migration of individual marks by making hand drawn records of the location of each mark throughout the duration of the study.

At 21 weeks post-marking (N = 7 dorsal, N = 9 ventral, N = 5 control salamanders were observed for this period of time), it was evident that VIE marks on the ventral surface were easier to read than marks on the dorsal surface. Salamanders added later to replace those that escaped had fewer observations, but the differences between treatments were still apparent. At that point, we opted to continue the experiment with only the ventrally marked group. We examined marks of the ventrally marked salamanders to 53 weeks post-marking (N = 6 completed the 53 weeks). From January–April 2007, we fed salamanders wingless *Drosophila melanogaster* weekly because salamanders were losing mass and few invertebrates were present in the leaf litter as potential prey items.

We averaged the readability of individual marks in salamanders by three week periods. We examined the effects of treatment (dorsal vs. ventral), time up to 21 weeks post-marking (7 periods), and a treatment × time interaction separately for each color of VIE with one-way repeated-measures analysis of variances (ANOVA; Zar 1996). In addition, we conducted one-way repeated-measures ANOVA that examined effects of VIE color, time post-marking and a color × time interactions up to 53 weeks (18 periods) for the ventrally marked group.

The evaluation of VIE marks for the dorsally and ventrally marked salamanders to 21 weeks post-marking could not meet the parametric assumption of normality for ANOVA, even after transformation of data. Similarly, the ANOVAs by color on the ventrally marked salamanders to 53 weeks were not normally distributed (Kolmogorov-Smirnov < 0.05) and were not improved by transformation. Therefore, we conducted one-way repeated-measures ANOVA on the ranked data (Conover 1999). No widely accepted non-parametric test exists that parallels a repeated-measures ANOVA with interaction terms, so we followed the suggestions of Conover (1999) to examine interaction terms and effects of time. Conover (1999) suggested that assessment of the parametric test be compared to the version conducted on the ranks, and if the results are very similar, to consider the parametric version to be a valid approximation of patterns in the data. We considered P-values of < 0.05 as significant. Program SAS 9.1 was used for all analyses.

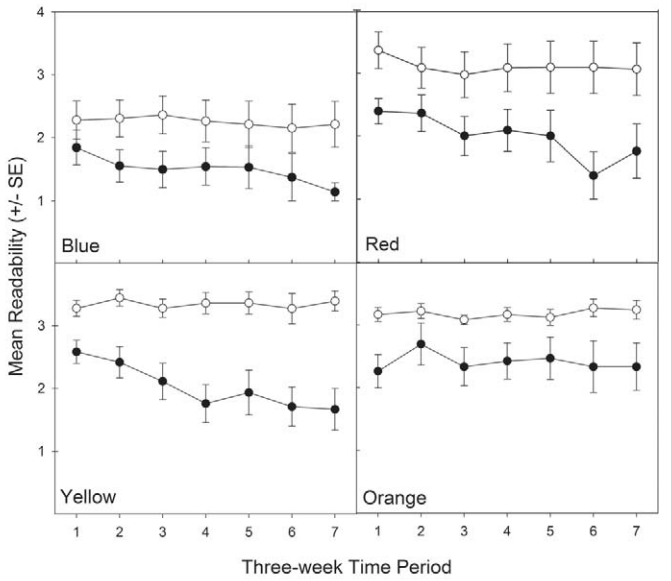

FIG. 2. Readability of Visible Implant Elastomer marks was greater in ventrally marked (open circles) *P. cinereus* than dorsally marked (filled circles) salamanders over seven three-week periods. Readability ranged from 1 (mark absent) to 4 (mark easily visible under fluorescent light).

Results.—Our results from the parametric versions of each repeated-measures ANOVA closely paralleled the results from each ANOVA on ranks. Thus, we considered the parametric versions to be reasonable and present their results. For each of the four colors, the mean visibility of marks was greater for the ventral treatment than dorsal (Blue: $F = 19.20$, $P < 0.001$; Red: $F = 33.95$, $P < 0.001$; Yellow: $F = 113.12$, $P < 0.001$; Orange: $F = 36.55$, $P < 0.001$) (Fig. 2). Additionally, for each color, there was not a significant effect of time ($P > 0.26$) or an interaction between treatment and time ($P > 0.24$).

For the analysis of only the ventrally marked salamanders, the F-statistics and associated P-values were very similar across parametric and non-parametric versions of the test, so that we present the parametric version. There was an effect of color ($F = 41.85$, $P < 0.001$), but no effect of time ($F = 0.18$, $P = 1.00$) and no interaction ($F = 0.13$, $P = 1.00$) for the ventrally marked salamanders (Fig. 3). Overall, blue was the most difficult to read and red, yellow, and orange were similar in their readability in our experiment (Fig. 3).

Migration of VIE marks occurred in 17% of salamanders (4% of marks), and 29% of salamanders had marks that broke into multiple pieces (7% of marks). Salamander mass decreased throughout the study period across all three treatments. By the end of the initial 21 week study period that encompassed dorsally, ventrally, and unmarked salamanders, mass of the control group (mean = -24.1, SE = 1.54%) decreased more than either the ventral (mean = -14.5, SE = 3.03%) or dorsal (mean = -16.1, SE = 2.79%) group.

Discussion.—Although several experiments have evaluated the effectiveness of VIE on salamanders, to our knowledge only one other study monitored VIE marks in salamanders for > 1 year (Davis and Ovaska 2001) and no research has compared colors and location of marks in salamanders. The results of our experiment suggest that VIE marks on the ventral surface are an appropriate and reliable tagging method for Eastern Red-backed Salamanders for at least one year. Dorsal markings were less visible, and should be considered less reliable identifiers than marking salamanders ventrally. The darker pigmentation on the dorsal side of our salamanders probably caused subcutaneous marks to be difficult to see even with the VI light. Of the elastomer colors examined in this experiment, orange, yellow, and red were easiest to read (Fig. 2, Fig. 3). Blue consistently was the most difficult color to read and the most likely to disappear in both dorsal and ventral treatments. Thus, we recommend that the color blue should be avoided as a choice of marks in future research of red-backed salamanders or other relatively darkly-pigmented amphibians. However, our results may be somewhat species-specific, so we suggest that researchers conduct a pilot test of readability for their study species prior to their investigation.

Not only were VIE marks relatively easy to identify in our study, but the readability of both dorsal and ventral marks did not change through time, as evidenced by the lack of an effect of time or treatment × time interaction for any of the four colors used. Therefore, the marks were as easy to read following the injections as at the end of the 21-week or 53-week period. Many field research projects use marks such as VIE to identify individuals for > 1 year. The researcher that marked salamanders was relatively inexperienced with VIE marking, so these results should be considered representative of a biologist newly trained to the technique. Our experiment provides evidence that VIE may be used to estimate parameters such as annual survival or recapture rates with little concern over mark loss.

In general, the results of our project are similar to research that compared VIE to other marking techniques or provided positive support for this method as a way to identify individual salamanders. For example, retention of VIE was greater than organic dyes in aquatic *Ambystoma tigrinum nebulosum* larvae (Harvey 2003) and was similar to photo-recognition in *Eurycea bislineata* (Bailey 2004). Further, VIE marks had a higher retention rate than toe clipping in *P. vehiculum* (Davis and Ovaska 2001). Visible im-

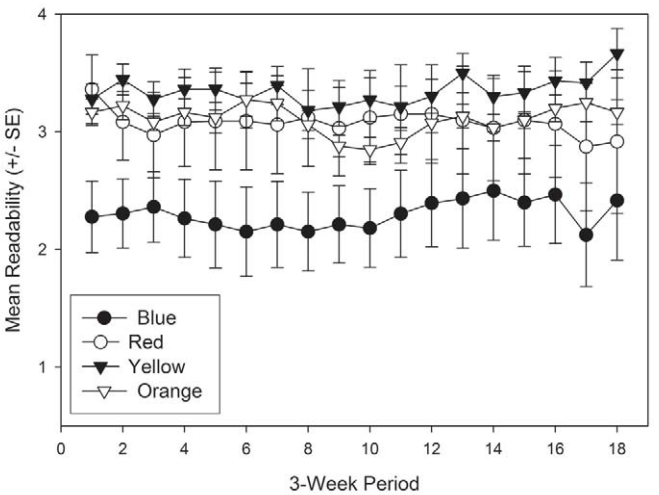

FIG. 3. Readability of Visible Implant Elastomer marks in *P. cinereus* that were ventrally marked and observed to 53 weeks post-marking was consistently less for the color blue than for red, orange, and yellow. Readability ranged from 1 (mark absent) to 4 (mark easily visible under fluorescent light).

plant elastomer marks were fully retained in *Eurycea bislineata* over a 15-week period (Marold 2001). However, in *Eurycea bislineata*, marks placed mid-body were confused with adjacent marks and the visibility of the marks varied due to pigmentation. Our study provides additional support that VIE marks are retained well without a decline in readability and offers specific recommendations to future researchers regarding locations and colors of elastomer.

Observed migration of marks implies that elastomers should be injected as far apart from one another as possible to prevent possible migration from confounding the individual identification. We observed migration and break-up of VIE marks during our study, but it is unlikely that wild Eastern Red-backed Salamanders would have higher incidents of mark movement or disintegration than we observed. *Plethodon cinereus* in our experiment were housed with soil, leaves, and a cover object so that daily activities of animals should have been similar to free-ranging salamanders. On several occasions study animals were observed burrowed in the soil or under the cover object, which may have facilitated movement of VIE marks from their initial location because of pressure applied from the substrate.

Acknowledgments.—We thank A. Brown and A. Roadman for laboratory support, W. Hopkins for providing research space, S. Orlofske for providing *D. melanogaster*. L. Michael, an anonymous reviewer, and S. DuRant for reviewing earlier drafts of this manuscript, and D. Stauffer for valuable statistical advice. Funding was provided by a USDA-NRI grant to C. Haas et al. (2005-35101-15363) and an AdvanceVT Doctoral Fellowship received by J. Homyack (SBE-0244916). All animal handling procedures were approved by the Animal Care and Use Committee of Virginia Tech (ACUC NUMBER 06-49-FIW) and appropriate state permits were obtained.

Monitoring Nesting Female Turtles after Dark

JOHN B. IVERSON
Department of Biology, Earlham College
Richmond, Indiana 47374-4095, USA
e-mail: johni@earlham.edu

Detailed studies of the nesting ecology of turtles can be hampered when turtles complete their nests after dark (e.g., Bowen et al. 2005). This limits observation without night telescopy, and makes it difficult to locate completed nests precisely and capture females for measurements after nest completion. The situation is exacerbated when a small number of observers are monitoring a large number of nesting females (e.g., Rowe et al. 2003). To overcome this problem, I evaluated several restraining methods (wire baskets, metal fences, buckets, and tubs). This report describes the restraining method that I found most successful. I have used this method for a decade in the Nebraska Sandhills.

At my study site, Painted Turtles (*Chrysemys picta*) nest almost exclusively between 1600 to 2200 h (Iverson and Smith 1993), and many Snapping Turtles (*Chelydra serpentina*) nest from 1800

to 0100 h (Iverson et al. 1997). When a female is seen leaving the marsh, I track her at a distance to her nest site. Occasionally a female will enter areas of tall grass which might make her difficult to follow. In this case I quickly (and with minimal disturbance) duct-tape a radiotransmitter to her shell, and track her from a distance for the next hour (being certain that she does not return to the marsh). I then locate her more precisely about an hour later, at which time she is usually nesting. Although time/personnel intensive (see also Rowe et al. 2003), this technique minimizes disturbance to females, and hence very few females fail to nest the first night they leave the marsh. However, with few observers it is extremely difficult to monitor more than a few nesting females without disturbance, and to locate nests precisely after nightfall.

As last light approaches (about 15 min after sunset), I very quickly cover the nesting turtle (Fig. 1) with a fiberglass tote box (65 × 46 × 25 cm deep; Consolidated Plastics, Twinsburg, Ohio). The box is oriented lengthwise to the turtle's body and centered directly over the nest cavity. The tub is then pushed firmly into the surrounding substrate (by standing on it) to allow minimal light passage under the edge of the tub. In the case of snapping turtles and painted turtles over 1 kg, I usually place a 20-liter bucket of soil or water on top of the tub to prevent the female from escaping when she has finished nesting.

At the time of restraint I note the stage of nesting (e.g., preoviposition, partial clutch laid, etc) and then return after an appropriate time and begin monitoring the tubs for the sound of the female bumping the side of the tub. The tub is then removed, the female returned to the lab for processing, and the nest is covered with predator-proof wire and mapped for further study (Costanzo et al. 2004). Palpation in the lab confirmed that each female laid her entire clutch (e.g., Thornhill 1982).

On cloudy evenings or when storms are approaching, I often deploy these tubs well before sunset, but when light levels are low. Female painted turtles that have begun depositing eggs before being covered have never abandoned their nests, though a few snapping turtles have aborted oviposition if only a few eggs were laid before covering. I have not experimented with covering turtles under high light conditions (i.e., earlier in the evening). Overheating might be an issue under those conditions.

FIG. 1. Restraining a nesting Western Painted Turtle at last light in the Nebraska Sandhills. Author on left; T. Muir on right.

The specific tubs I use are wire-reinforced and expensive (ca. $60 each), but they have the added advantage of nesting within each other for transport. In addition, when their orientation is reversed, they are stackable and functional as holding bins for turtles awaiting processing (including induction of oviposition in other females; Iverson and Smith 1993). Although cheaper tubs are available, I have found them to be cost effective in the long-term, as I have never had one break or fail in over 20 years of heavy use. This technique has been used successfully with female snapping turtles up to 12 kg and painted turtles up to 1200 g. It should work with other turtles that nest on relatively flat terrain and into the late evening.

Acknowledgments.—I thank T. Muir and P. Baker for their help in experimenting with and perfecting this technique. J. Tucker provided comments on the manuscript. My research was conducted under the authority of permits issued by the Nebraska Game and Parks Commission and the Crescent Lake National Wildife Refuge. Treatment of all animals was in accordance with the ethical principles outlined in the SSAR Guidelines for Use of Live Amphibians and Reptiles in Field Research.

AMPHIBIAN CHYTRIDIOMYCOSIS GEOGRAPHIC DISTRIBUTION

A special section on "Amphibian Chytridiomycosis Geographic Distribution" makes its debut in this issue of *HR*. This section will offer a timely outlet for streamlined presentation of research exploring the distribution and prevalence of the amphibian chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*). *Bd* is an emerging infectious disease linked to mass mortality of amphibians worldwide, yet *Bd* detections in amphibians with no symptoms also are known in many areas. To aid in our understanding of the scope of this issue, we encourage submission of studies on *Bd* geographic distribution, including research on individual species or groups of species, wild or captive animals, native or non-native species, live animals or museum specimens, environmental samples, and findings with no *Bd* detections. We ask authors to: 1) restrict the Introduction of their paper to a **maximum** of two paragraphs to highlight the context of their study; 2) briefly include both field and laboratory Methods; 3) present Results in a Table, although a map also might be very useful, and limited text; and 4) have a short discussion of a **maximum** of three paragraphs to touch upon key findings. Please consider including the following information in submissions: coordinates and de-

scription of sampling areas (or please note if locations are extremely sensitive to reveal, and provide general area instead); positive and negative results; disposition of voucher specimens; date of specimen collection; name of collaborative laboratory or researcher conducting histological sections or PCR analyses; and names of cooperative land owners or land management agencies. We aim to expedite the review and publication process! Please e-mail submissions directly to Associate Editor, Dr. Dede Olson: dedeolson@fs.fed.us.

The fungus *Batrachochytrium dendrobatidis* is the disease agent responsible for chytridiomycosis in amphibians and has been associated with amphibian declines and extinctions around the world (Berger et al. 1998; Lips et al. 2006). While there is evidence that *B. dendrobatidis* spread around the world in the latter part of the last century (Ouellet et al. 2005; Skerratt et al. 2007), the full extent of its current distribution remains unclear. Information on the spatial extent of *B. dendrobatidis* will help us understand the threat posed by chytridiomycosis to amphibians.

Batrachochytrium dendrobatidis has recently been detected in *Rana sylvatica* on the Kenai National Wildlife Refuge in Alaska (Reeves and Green 2006) and in introduced *Rana catesbeiana* on Vancouver Island, Canada (Garner et al. 2006). It is predicted to occur all along the northwest coast of North America (Ron 2005), but no other cases of amphibians with *B. dendrobatidis* have been reported in this region. Here, we report the results of surveys of 27 native amphibian populations at 22 sites spanning the northwest coast from Vancouver Island in British Columbia, Canada, north to the vicinity of Skagway, Alaska, USA (Fig. 1).

In the summers of 2005 and 2006, we captured adult, juvenile and larval amphibians by hand or dip net and sampled them for *B. dendrobatidis* by swabbing a rayon swab (Medical Wire, MW113) over the body of each individual. Frogs were held separately prior to swabbing and technicians wore a new pair of gloves for each individual handled. As the frog was restrained, the swab was firmly rubbed back and forth 30 times over the drink patch and mouth and was rubbed on the webbing between each toe. The swab was then air dried for 30 minutes and stored in a pre-labeled (cryo-

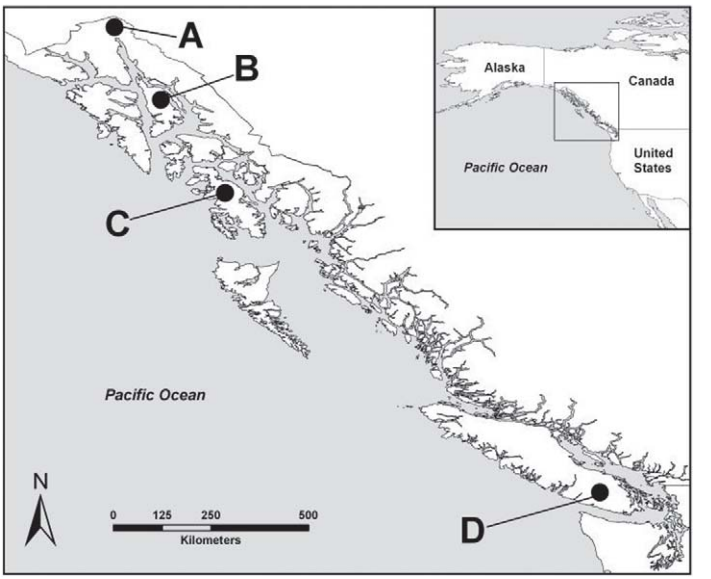

FIG. 1. Study areas where amphibians were sampled for the presence of *Batrachochytrium dendrobatidis* in 2005 and 2006 in Alaska, USA (Areas A, B, and C) and British Columbia, Canada (Areas A and D).

TABLE 1. The number of adult, juvenile, and larval anurans that tested positive (in bold) or negative for the presence of *Batrachochytrium dendrobatidis* in 2005–2006. See Fig. 1 for Study Area locations. The species examined were *Bufo boreas* (BUBO), *Rana luteiventris* (RALU), *R. sylvatica* (RASY), and *R. aurora* (RAAU).

babies labels, Diversified Biotech, 9188-2000) sterile, screw cap 1.5 ml microcentrifuge tube (Fisher # 05-669-12). In most cases vials were shipped to the laboratory for analysis within 2 weeks of sampling but in some cases were frozen and held for up to 6 months. Each swab was analyzed individually for the presence of *B. dendrobatidis* using a real-time Taqman PCR assay at the U. S. Geological Survey, National Wildlife Health Center (Boyle et al. 2004). All field gear was cleaned with a brush and water and then sprayed with a dilute bleach solution between each sampling location.

Of 242 amphibians swabbed, 52 were positive for *B. dendrobatidis* (Table 1). We found *B. dendrobatidis* on individuals from 11 of 22 populations and in 3 of the 4 study areas (A, C, and D). All but 2 of the positive results were for *Bufo boreas* adults or juveniles. The other two positives were for *Rana aurora* adults. No *R. luteiventris* or *R. sylvatica* were positive. We did not find any frogs that were dead or appeared to be sick. For populations with at least one positive animal and with N 5 adults and juveniles, the percent of adults and juveniles testing positive averaged 34% and ranged from 10 to 80%.

There is increasing documentation that *B. dendrobatidis* is geographically widespread (Berger et al. 1998; Carnaval et al. 2006; Garner et al. 2005; Lips et al. 2006; Ouellet et al. 2005; Pearl et al. 2007; Pounds et al. 2006). Our results add to this evidence and verify the prediction of Ron (2005) that this pathogen should occur along the northwest coast of North America.

Acknowledgments.—This work was funded by the U. S. Geological Survey's Amphibian Research and Monitoring Initiative. We complied with all applicable institutional animal care guidelines and obtained appropriate research permits to do this work. Use of trade names does not constitute endorsement.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 38, Number 1 (March 2007).

CAUDATA

AMBYSTOMA ANNULATUM (Ringed Salamander). **CAVE USE.** Numerous species of salamanders are known to utilize caves for their entire or partial life history requirements, such as foraging and feeding, refugia from summer drought or winter cold conditions, and/or reproduction, while others are considered accidentals (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 587 pp.). The karst area of the Ozark ecoregion in Arkansas, Missouri, and Oklahoma contains thousands of caves that are known to support a modest diversity of salamander species, especially plethodontids (Black 1973. Proc. Oklahoma Acad. Sci. 53:33–37; McDaniel and Gardner 1977. Proc. Arkansas Acad. Sci. 21:68–71; Graening and Brown 2000. Status Survey of Aquatic Cave Fauna in Arkansas. Arkansas Game and Fish Commission Rept., 43 pp.; Elliott and Ireland 2002. *In* Proceeding of the National Cave and Karst Management Symposium, pp. 123–130. Tuscon, Arizona; Briggler and Prather 2005. Am. Midl. Nat. 155:136–148). Occasionally, ambystomatid salamanders are observed within caves; two species (*Ambystoma tigrinum* and *A. maculatum*) have been reported in caves within the Ozark ecoregion (Black 1969. J. Herpetol. 3:183–184; McDaniel and Gardner, *op. cit.*; Bill Elliott, pers. comm.). Herein, we report the first known documented sighting of *A. annulatum* in a cave in southern Missouri.

On 2 Oct 2003, an adult *A. annulatum* was observed in Mud Spring Cave, a U.S. Forest Service-owned cave in the Willow Spring District, Mark Twain National Forest, ca. 4 m from the cave entrance (R. Rimer, pers. comm.). Return to the cave on 10 Jan 2004 by both authors yielded another finding regarding the presence of *A. annulatum* in Mud Spring Cave. A pool within the cave contained 18 larval *A. annulatum*. The pool starts ca. 30 m from the cave entrance and extends ca. 35 m further into the cave.

There were two size classes of *A. annulatum* larvae; sixteen of the larvae were ca. 20 mm TL while the remaining 2 larvae were ca. 30 mm TL. Two larvae were removed and allowed to transform for identification confirmation. One specimen was deposited in the Dean E. Metter Memorial Collection, University of Missouri, Columbia (UMC 7969). We would also like to document an unpublished observation of an adult *A. annulatum* discovered in a pit cave (Whiskey Pit Cave, Christian Co.) on 10 Oct 1984 (G. Gardner, pers. comm.). Gardner (pers. comm.) stated that this individual likely fell into the pit entrance of the cave and was trapped. To our knowledge, these accounts are not only the first documentations of *A. annulatum* use of caves, but the first account of the species using a cave pool for reproduction. The only other ambystomatid known to utilize caves for reproduction in the Ozark ecoregion is *A. tigrinum* (Black 1969, *op. cit.*).

We extend our thanks to Gene Gardner and Bill Elliott for providing unpublished information.

RIMER**, Missouri Dept. Conservation, 551 Joe Jones Blvd, West Plains, Missouri 65775, USA (e-mail: rhonda.rimer@mdc.mo.gov).

AMBYSTOMA MACULATUM (Spotted Salamander). **MIGRATION/BREEDING OBSTRUCTION.** Ambystomid salamanders in the northeastern United States migrate to vernal pools to breed during the first warm rains of spring. These shallow, ephemeral pools form from snowmelt and precipitation in the spring, and typically dry up by late summer. This keeps vernal pools free of fish which could prey on amphibian eggs and larvae, but allows enough time for the eggs to hatch (ca. 6–8 weeks after deposition) and larvae to metamorphose (ca. 2–4 months). (Kenney and Burne 2000. A Field Guide to the Animals of Vernal Pools, Massachusetts. Div. Fisheries and Wildlife, 73 pp.).

Migrating salamanders can face a number of hazards en route to breed in vernal pools including barriers such as houses, shopping malls and roads (Kenney and Burne 2000, *op. cit.*). Roads in particular present a hazard to migrating salamanders, both as barriers that could prevent movement and through mortality from motor vehicles (Grant et al. 2004. Wood Frog and Spotted Salamander Double-Observer Egg Mass Count Protocol, U.S. Geol. Surv.).

On the evening of 2 April 2004 at ca 2200 h while walking on a dirt road in a wooded area in Groton, Massachusetts (42°37.112'N, 71°33.018'W), we observed several *Ambystoma maculatum* that seemed to be exhibiting breeding behavior in puddles on the road. There was construction going on nearby and straw bale barriers were lining one side of the dirt road. Straw bale barriers are often used at construction sites to prevent sediment runoff into adjacent wetlands and other natural habitats (V. Turano, pers. comm.). Upon closer inspection, we discovered several more *A. maculatum* wandering along the base of the straw bale barriers, presumably trying to find a way to the vernal pool sites on the opposite side of the road. This presumption was further strengthened by the discovery of an *A. maculatum* on top of a straw bale barrier.

On 3 April 2004, the Groton Conservation Committee was contacted to remedy the situation. After discussions with the Conservation Committee some of the straw bale barriers were removed to allow passage of the salamanders to the vernal pools.

Our observations suggest that if barriers prevent salamanders from reaching their vernal pool breeding sites, the animals may attempt to breed in temporary puddles they encounter on roads. This could present a hazard, as these shallow puddles might not last as long as the developing eggs or larvae would need to mature. This phenomenon has been referred to as a potential "ecological trap" (deMaynadier and Hunter 1995. Environ. Rev. 3:230–261).

This observation also presented a paradoxical situation where a conservation practice—placement of straw bale barriers to prevent runoff at construction sites—inadvertently caused a conservation problem—the creation of a barrier to salamander migration and breeding. Local conservation officers should be aware of this in areas where salamander migration might occur, and consider temporarily removing straw bale barriers to allow adult salamanders access to vernal pool breeding sites in the spring, and later in the season, to permit natal dispersal of metamorphs back to surrounding upland habitat.

We thank Vincent Turano, Merrimack College, for information on the use of straw bale barriers at construction sites.

Submitted by **DONALD LYMAN, JR.**, Department of Biology, Merrimack College, 315 Turnpike Street, North Andover, Massachusetts 01845, USA; and **CHRIS M. SHAFFER**, 419 Martins Pond Rd, Groton, Massachusetts 01450, USA.

DESMOGNATHUS QUADRAMACULATUS (Black-bellied Salamander). **PREDATION**. Relatively little information exists on the natural predators of adult forms of *D. quadramaculatus*. The known predators include shrews (*Blarina brevicauda*), garter snakes (*Thamnophis* spp.), and larger conspecifics (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Instit. Press, Washington DC.; Lannoo 2005. Amphibian Declines: The Conservation Status of United States Species. University of California Press, Berkeley, California.). Here I report an adult *D. quadramaculatus* being preyed upon by an adult Northern Watersnake (*Nerodia sipedon*) on 8 May 2004 at 1130 h. The predation event occurred in a headwater stream in the Highlands Ranger District of the Nantahala National Forest, North Carolina (17S 0297732E, 3878045N).

Ducey and Brodie Jr. (1983. Copeia 1983:1036–1041) found that many salamanders will remain immobile when contacted by the head or body of a predatory snake. Once a *D. quadramaculatus* feels a tongue flick or bite, it will immediately bite the predator and begin to twist its body in an attempt to free itself from a predator (Brodie Jr. 1978. Copeia 1978:127–129). Brodie Jr. (1978, *op. cit.*) found that if a predator approached a *D. quadramaculatus* from the side or rear, the salamander would flip its body off the ground using its tail and land facing the predator. The adult *D. quadramaculatus* I observed was sitting on a semi-submerged log facing downstream on an overcast day. After ca. 3 min I noticed a *N. sipedon* slowly moving down the stream and as it approached the salamander it began to tongue flick rapidly. The *N. sipedon* slowly approached the *D. quadramaculatus* from the rear right-side, but never made contact with the salamander with its body or

tongue. Once the head of the *N. sipedon* was parallel with the head of the *D. quadramaculatus*, the snake stopped and began to tongue flick once again without contacting the salamander. The *D. quadramaculatus* remained completely motionless. After ca. 1 min, the *N. sipedon* rapidly struck to its left side and grasped the *D. quadramaculatus* by the head. The *D. quadramaculatus* began twisting its body but was unable to free itself and the *N. sipedon* swallowed the salamander in 2 min. After swallowing the salamander, the *N. sipedon* continued its path downstream. It has been speculated that *N. sipedon* are predators of *D. quadramaculatus*, but to my knowledge this is the first documentation of such an event.

EURYCEA LUCIFUGA (Cave Salamander). **DIET**. Crowell (1981. Unpubl. Ph.D. diss., University of Arkansas, Fayetteville) provides a detailed account of the feeding habits of *Eurycea lucifuga*, *E. longicauda*, and *Plethodon glutinosus* in select caves from northwest Arkansas. In stomach content analyses of these species, he identified cave cricket remains in two of 128 *E. lucifuga*, three of 81 *E. longicauda*, and none of 65 *P. glutinosus* examined. Based on our review of the literature, Crowell (1981, *op. cit.*) is the only study that specifically identifies cave crickets in the diet of *E. lucifuga*.

White (1997. Unpubl. Masters thesis, Austin Peay State University, Clarksville, Tennessee. 81 pp.) conducted an extensive ecological study of *E. lucifuga* in select caves of central Kentucky and Tennessee. On 16 Feb 1995 at 2000 and 2200 h, during a 24-h census of the visible *E. lucifuga* population at the Great Onyx entrance of Mammoth Cave (Mammoth Cave National Park, Edmonson County, Kentucky) we observed one *E. lucifuga* with *Hadenoecus subterraneus* (cave cricket) hind legs protruding from its mouth. This individual represents 2.6% of the maximum number of *E. lucifuga* (N = 38) observed during this 24 h period.

Although Crowell (1981, *op. cit.*) found dipterans to be the dominant prey item, by total number, for all three species of salamanders he often found total prey volume to be dominated by a single large prey item. We found *H. subterraneus* and to a lesser degree *Ceuthophilus stygius* (camel cricket) to be quite common at the Great Onyx entrance of Mammoth Cave during our study period. These two species of crickets represent the maximum prey size class Crowell (1981, *op. cit.*) documented for *E. lucifuga* and they are likely an important prey item for *E. lucifuga* where they co-occur.

Fieldwork leading to this observation was supported by Austin Peay State University Center for Field Biology.

GYRINOPHILUS PORPHYRITICUS DANIELSI **(**Blue-Ridge Spring Salamander) and ***DESMOGNATHUS MONTICOLA*** **(**Seal Salamander). P**REDATION/REGURGITATION.** *Gyrinophilus porphyriticus* ssp. are known to be successful predators of heterospecific salamanders (Petranka 1998. Salamanders of the United States and Canada, Smithsonian Inst. Press, Washington D.C. 587 pp.). In the southern Appalachian Mountains, 47% of all identifiable stomach contents of *G. p. danielsi* were salamanders (Bruce 1972. Herpetologica 28:230–245). Though a variety of salamander species have been described as prey of *Gyrinophilus* spp., *Desmognathus monticola* has not been included (Petranka 1998, *op. cit.*). Herein I describe the consumption and subsequent regurgitation of a *D. monticola* by *G. p. danielsi*.

On 3 June 2006 at 1000 h a *G. p. danielsi* (SVL 93 mm, total length 138 mm, 10.8 g) and a *D. monticola* (SVL 36 mm, TL 65 mm, 1.0 g) were captured in a trap along with three *Eurycea wilderae* larvae. The larger salamanders were placed in the same 1-quart Ziploc® bag with a small amount of water while the larval salamanders were weighed and measured. In the ca. 4 min it took to measure and release the larval salamanders, the *G. p. danielsi* had completely consumed the *D. monticola*, which was only evident because of the distended abdomen of the *G. p. danielsi*. I proceeded with my routine length measurements of the *G. p. danielsi*, but the jostling and momentary restraint of the salamander caused it to regurgitate its recent meal. The regurgitated *D. monticola* appeared to be unaffected by the process, aside from a few superficial skin abrasions. The *D. monticola* was then measured and both salamanders were released.

Gyrinophilus porphyriticus ssp. are gape-limited predators (Formanowicz and Brodie 1993. Herpetologica 49:265–270), restricting the size of ingestible prey. Though no gape or circumference measurements were made of the two salamanders, this appeared to be a rather impressive feat of ingestion as the total length of the *D. monticola* was ~70% of the snout–vent length (i.e., approximate abdominal cavity) of the *G. p. danielsi*. Further, this single meal comprised almost 10% of its entire body weight. The *G. p. danielsi* had no difficulty ingesting the smaller salamander, but my observation may have been an opportunistic feeding as both were placed in close proximity within a confined area. Similar observations of such feedings have been reported by Wright and Haber (1922. Copeia 31–32).

NECTURUS MACULOSUS (Mudpuppy). **BODY SIZE AND DIET.** On 11 Feb 2004 a large 38 cm TL, *Necturus maculosus* was captured by hook and line angling through the ice at Put-in-Bay, Ohio at 41°39.285'N, 82°49.119'W. This is the largest specimen reported from Ohio (Pfingsten 1989. Salamanders of Ohio. Ohio Biol. Survey Bull. VII [2]). The mudpuppy was placed in an empty 22.7-liter bucket filled with lake water and kept for overnight observation. The specimen regurgitated 10 shiners (*Notropis* sp.) and one adult Round Goby (*Neogobius melanostomus*). Minimal digestion aided in the positive identification of the fishes. The goby was ca. 10 cm total length. Although *N. maculosus* has been

documented to feed on varying amounts and species of fish (Cagle 1954. Copeia 257–260; Hamilton 1932. Copeia 83–86; Harris 1959. Field and Lab. 27:105–111; Lagler and Goellner 1941. Copeia 96–98) we believe this is the first documentation of *N. maculosus* foraging on the invasive Round Goby.

Submitted by **MATT A. THOMAS**, Franz Theodore Stone Laboratory, 878 Bayview Avenue, Pit-in-Bay, Ohio 43456, USA (e-mail: Thomas.347@osu.edu); **KRISTIN M. STANDFORD**, Northern Illinois University, Department of Biological Sciences, DeKalb, Illinois 60115, USA (e-mail: kstanford@niu.edu); and **KENT BEKKER**, Bowling Green State University, Department of Biology, Bowling Green, Ohio 43402, USA and Department of Herpetology, Toledo Zoological Society, 2700 Broadway, Toledo, Ohio 43609, USA (e-mail: herpers@toledozoo.org).

PSEUDOTRITON RUBER RUBER (Northern Red Salamander). **POLYMELIA**. Polymelia, the growth of an extra limb (Meteyer 2000. Field Guide to Malformations of Frogs and Toads with Radiographic Interpretations. Biol. Sci. Rept., USGS/BRD/BSR-2000-0005, Madison, Wisconsin), has been documented extensively in anurans. Observations of polymelia in salamanders have rarely been reported and primarily restricted to the genus *Ambystoma* (North American Reporting Center for Amphibian Malformations website; http://frogweb.nbii.gov/narcam/). Few malformations have been described in stream salamanders and generally reported a lack of proper limb growth (*Desmognathus fuscus:* anopthalmia, ectromelia, brachydactyly; and *Eurycea cirrigera:* hemimelia, ectrodactyly, and brachydactyly; NARCAM website). We describe polymelia in a larval *Psuedotriton ruber* collected from a stream at Cowan's Ford Wildlife Refuge in Mecklenburg County, North Carolina (3914850N, 0503155E Zone 17). The *P. ruber* larva (SVL 38 mm, TL 60 mm) was captured using a funnel trap in a first-order stream on 20 Nov 2006. The malformation occurred on the left foreleg, which appeared to be non-functional. At the elbow, two sets of radius and ulna emerge, one of which also appeared to have a rotational malformation (Appendage 1; Fig. 1). Appendage 1 appeared to have further malformations resulting in only 2 phalanges, but appendage 2 had four fully formed metatarsal bones and phalanges (Fig. 1). This larva is the only salamander of 540 captured individuals we found with any noticeable malformation. This represents the first report of multiple limbs in a stream salamander and the only known description of a malformation in *P. ruber.*

TRITURUS MARMORATUS (Marbled Newt). **NEWT PREDATION**. *Triturus marmoratus* feeds on earthworms, insects, and the eggs and larvae of amphibians (Salvador and Garcia-Paris 2001. Anfibios Españoles. Canseco Eds. 270 pp.). Herein I report predation of Bosca´s Newt (*T. boscai*) by *T. marmoratus* in NW Spain.

On 15 March 2006 some *T. marmoratus* were captured in our traps while monitoring the European Pond Turtle (*Emys orbicularis*) in Gandaras de Budiño wetland, NW Spain. During manipulation to release these newts, a large female regurgitated an almost intact *T. boscai*. As Salvador and Garcia-Paris (2001, *op. cit.*) stated, the diet of *T. marmoratus* in northern Spain includes eggs and larvae of other amphibians including *Bufo calamita*, *Rana perezi*, and *Pelobates cultripes*. Only an exceptional case of adult newt consumption is reported involving an adult Alpine Newt (*Triturus alpestris*). Adult *T. marmoratus* in NW Spain reach more than 150 mm TL, while *T. boscai* remains smaller, reaching 90 mm TL. Thus, *T. boscai* could be potential prey for *T. marmoratus*.

ANURA

ATELOGNATHUS PATAGONICUS (NCN). **PREDATION**. Numerous species prey on larval and post-metamorphic anurans, including spiders, adults and larvae of aquatic insects, fishes, birds, and mammals (Duellman and Trueb 1994. Biology of Amphibians. Johns Hopkins University Press, Baltimore, Maryland. 670 pp.; Formanowicz 1986. Herpetologica 42:367–373; Heyer et al. 1975. Biotropica 7:100–111; Kokubum and Zacca 2003. Herpetol. Rev. 34:232–233; Prado 2003. Herpetol. Rev. 34:238–239). *Atelognathus patagonicus* occurs in Laguna Blanca National Park and the surrounding area of Neuquén Province, Argentina. The species was recently listed as Endangered (Lavilla et al. 2000. Categorización de los Anfibios y Reptiles de la República Argentina. Asociación Herpetológica Argentina. 97 pp.). Habitats are semi-permanent to permanent ponds and lakes. Species of aquatic and semi-aquatic birds, including grebes (*Podiceps*), Black-necked Swans (*Cygnus melancoryphus*), and Chilean Flamingos

(*Phoenicopterus chilensis*) also live at these sites.

Herein we report observations of predation on *A. patagonicus* by four species of birds. During a survey along the NW shore of Laguna Verde—a permanent pond 0.17 km^2 (39°0'S, 70°23'W; 1282 m elev.) in Laguna Blanca Park—we observed predation on tadpoles and post-metamorphic *A. patagonicus* by *Podiceps occipitalis* (Silvery Grebe) and *P. rolland* (White-tufted Grebe). Between 1120–1220 h on 28 Dec 2003, we observed 22 captures by these grebes. Seven *P. occipitalis* captured 6 tadpoles and 15 post-metamorphic frogs. One *P. rolland* captured one post-metamorphic *A. patagonicus*. A grebe would dive underwater for as long as two minutes, and then emerge with a prey item in its beak; tadpoles were held by their tails and frogs by one of their legs. The grebe would slap the prey against the water surface before swallowing it headfirst. We observed similar acts of predation by these two species on 29 and 30 Dec 2003, between 900 and 1700 h. At Laguna el Hoyo—another permanent pond in Laguna Blanca Park—two other birds, *Larus maculipennis* (Brown-hooded Gull) and *Oxyura ferruginea* (Andean Ruddy Duck), were observed preying on *A. patagonicus* on 15 Jan 2002. In these two lagoons the most commonly observed predators are birds. Hence, it is important to further investigate the interaction between bird predation and *A. patagonicus* populations.

BUFO AMERICANUS (American Toad). **ALGAL SYMBIOSIS.** Recently, Tumlison and Trauth (2006. Herpetol. Cons. Biol. 1:51–55) reported a mutualistic relationship between algae and *Bufo* tadpoles in Arkansas. Prior to this report, algae/amphibian associations were only known to occur with amphibian egg masses. The initial observations were of relationships between an alga and *Ambystoma maculatum* (Spotted Salamander) egg masses (Gilbert 1942. Ecology 23:215–227; Orr 1888. Quart. J. Microsc. Sci. 29:257–259). Gilbert (1944. Ecology 25:367–369) described the association between the unicellular alga, *Oophila amblystomatis*, and developing *A. maculatum* embryos as symbiotic. The results of the symbiosis are greater survivorship and growth in the developing salamanders (Gilbert 1944, *op. cit.*), although Anderson (1971. Herpetol. Rev. 3:76) reported negative impacts on the developing embryos due to the presence of algae in a developing *A. tigrinum* (Tiger Salamander) egg mass.

Algae have been associated with egg masses of other species of *Ambystoma*, including *A. jeffersonianum* (Jefferson's Salamander; Gilbert 1942, *op. cit.*), *A. tigrinum* (Anderson 1971, *op. cit.*), and *A. gracile* (Northwestern Salamander; Marco and Blaustein 2000. J. Herpetol. 34:617–621.), as well as other amphibians, including *Rana sylvatica* (Wood Frog; Gilbert 1942, *op. cit.*). Algae are found not only associated with multiple amphibian species, but also distributed broadly across the United States (Cliburn and Ward 1963. Am. Midl. Nat. 69:508–509; Gilbert 1942, *op. cit.*; Marco and Blaustein 2000, *op. cit.*; Smith 1950. The Freshwater Algae of the United States. McGraw-Hill, New York.).

The phenomenon of algae aggregations on the skin of live tadpoles also appears to be distributed across several species, including toads and treefrogs (Tumlison and Trauth 2006, *op. cit.*) and geographically. While conducting a diurnal amphibian survey at Rose Pond Conservation Area, Clark County, Missouri, on 19 June 2006, we captured several *Bufo americanus* tadpoles. These tadpoles exhibited bright green patches on the ventral and lateral portions of the body, similar to those described by Tumlison and Trauth (2006. *op. cit.*). The tadpoles were in a shallow puddle (44 × 7 m,

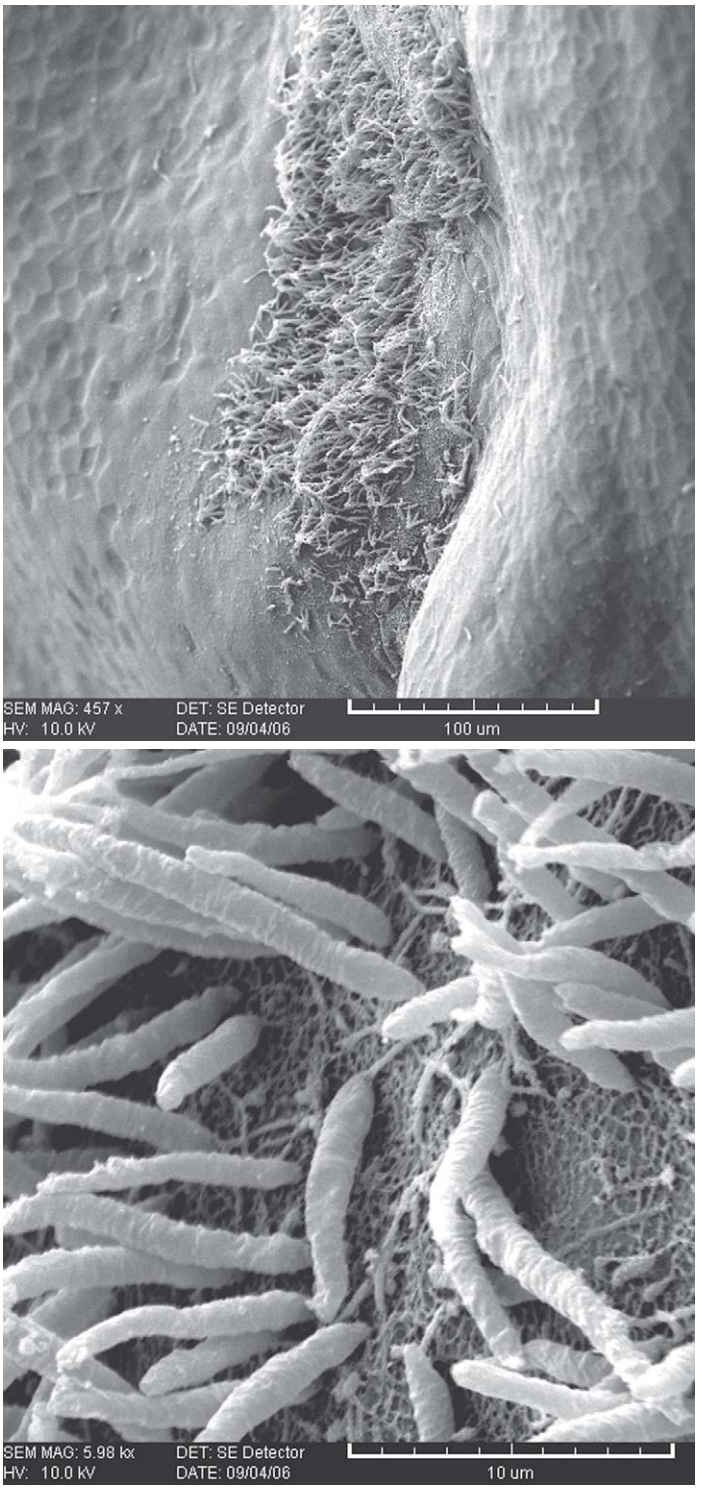

FIG. 1. Lateral aggregations of the biflagellated green alga (*Chlorogonium*) on a *Bufo americanus* tadpole.

max depth 0.27 m) that was devoid of vegetation in an open field. The water was slate gray, water temperature 32°C, dissolved oxygen content was 6.0 ppm. The pool was also inhabited by tadpoles of *Acris crepitans* (Northern Cricket Frog), *Rana pipiens* complex (Leopard Frog) and *Hyla versicolor/chrysoscelis* complex (Gray Treefrog/Cope's Treefrog), but none of these appeared to have the green algal patches. The *B. americanus* tadpoles were collected live, examined, and photographed with a stereomicroscope. The tadpoles were preserved in 10% formalin. The areas of the skin where green patches had been observed on the tadpoles were examined using a scanning electron microscope (Fig. 1). The images revealed patches of biflagellated algae that are similar to *Chlorogonium*, the same algae found on the tadpoles reported by Tumlison and Trauth (2006, *op. cit.*).

The phenomenon of algal symbiosis in amphibians is not limited to one life stage, and, as our observations indicate, the association between algae and tadpoles appears to occur in multiple species across a broad geographic range. If the species patterns were similar to those seen between algae and egg masses, we would expect algal-tadpole associations within other frog taxa beyond bufonids as well. The association of the algae and tadpole may have species- or site-dependent impacts or benefits, as is the case with algal associations with amphibian egg masses, and certainly warrants further examination.

We thank Ronn Altig, Jef Jaeger, Ray Semlitsch, and Chris Shulse for comments that improved this manuscript.

COCHRANELLA SAVAGEI (Savage's Glass Frog). **REPRODUCTION.** The family Centrolenidae is composed of ca. 120 species with a Neotropical distribution, mostly in mountainous areas (Zug et al. 2001. Herpetology: An Introductory Biology of Amphibians and Reptiles, 2nd ed. Academic Press, San Diego, California. 630 pp.). Reproduction is characterized by oviposition in arboreal or terrestrial substrates over small to large streams (Duellman and Trueb 1986. Biology of Amphibians. McGraw Hill, New York. 670 pp.). Although the reproductive mode is well established, basic aspects of the reproduction and natural history of many species have not been published. Here, we document clutch size, embryonic development, body size of hatchlings, parental care, and egg mortality in *Cochranella savagei*. This is a small frog (mean SVL 23.6 mm for females and 21.1 mm for males), which occurs in the Sub-Andean forest of the central and western Andes of Colombia (Ruíz-C. and Lynch 1991. Lozaina 59:1–18).

These observations were recorded at La Albania (five days during March 2006) and the Reserva Forestal Bosque de Yotoco (3 trips, each 10 days long during March, April, and June 2006). These localities are separated by ca. 5 km and are on the western slope of the western cordillera of Colombia in the Department of Valle del

TABLE 1. Data recorded for 9 egg clutches of *Cochranella savagei*. Clutches 1–3 were located at La Albania, 4–9 were located at Bosque de Yotoco. Hatching data were recorded in the six clutches marked with an asterisk (*). All measurements in mm.

Clutch	Male SVL	No. of eggs	Diameter of eggs (mean ± SD)		Days of monitoring
			First record	Last record	
1	22.4	17	4.96	5.10	3
2	20.0	19	3.93	4.21	3
3	—	18	5.00	5.20	2
4 *	23.1	18	3.90	6.40	10
5 *	22.5	19	4.48	6.36	8
6 *	23.0	15	4.90	6.29	9
7 *	23.3	19	4.10	6.11	10
8 *	22.4	16	4.56	6.23	9
9 *	2.50	18	5.00	6.00	9

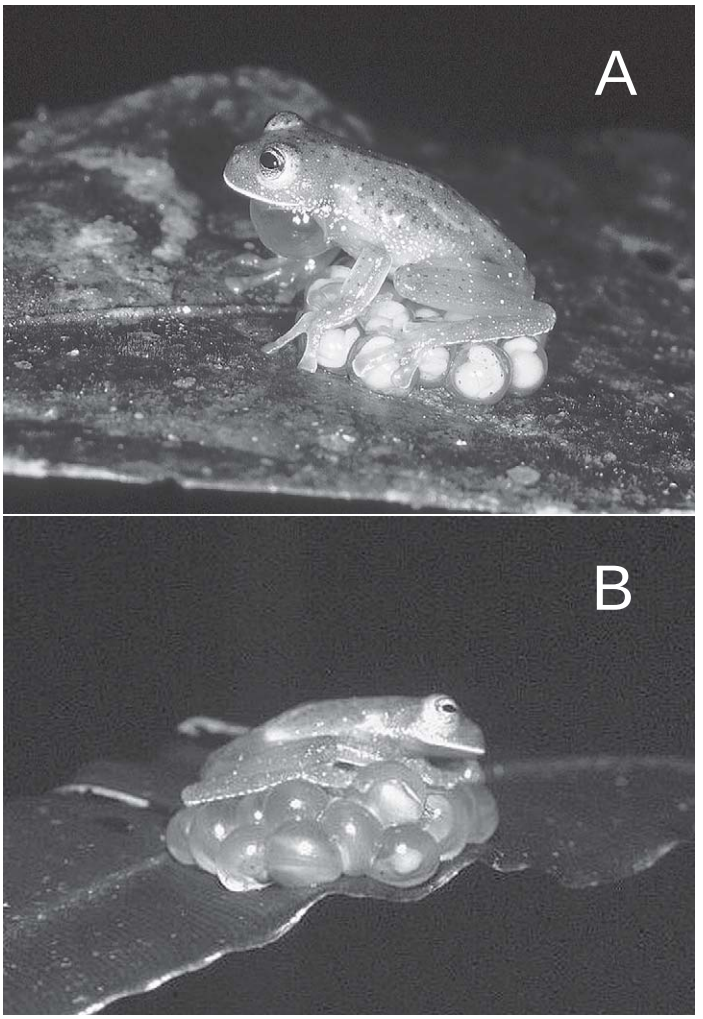

FIG. 1. Parental care and egg size changes in *Cochranella savagei*. A) Clutch with one day of development; males call above eggs or beside them to attract additional females; B) Embryos at 10 days of development, near hatching (note the eye development in embryos).

Cauca. During the first observation of each clutch, the number and diameter of eggs was counted, and the SVL of the male guarding the clutch was recorded. The number and diameter of eggs and the development of embryos was monitored during subsequent visits. When embryos of two clutches were near hatching they were captured and measurements taken (Hayes 1983. Herpetol. Rev. 14:115–116); developmental stage (Gosner 1960. Herpetologica 16:183–190) was also determined. The hatchlings were released at the capture site.

Nine clutches of *C. savagei* were recorded (Table 1). All clutches were observed on the top surface of leaves from 80–300 cm above ground. The mean number of eggs per clutch was 18 (sd = 1.41, N = 9). Mean diameter varied from 4.58 mm (sd = 0.46, N = 9) when they were 1–2 days old, to 6.4 mm (sd = 0.18, N = 6) when the embryos were close to hatching. Hatching occurred 10–12 after laying. The hatching of embryos in one clutch was not simultaneous (F. Vargas, pers. obs.). Embryos hatched at Stage 24 (Gosner 1960, *op. cit.*) with a mean size (body + tail) of 11.92 mm (sd = 0.63, N = 27). Egg predation was not recorded. Five eggs (belonging to two different clutches) did not develop. Parental care was continuous; the males were above or beside the eggs (Fig. 1) and after diurnal rains they called to attract females. However, we did not record a male at two or more clutches.

The Sub-Andean forest is one of the most threatened habitats in Colombia due to deforestation, fragmentation, and the development of urban complexes (Renjifo 1999. Conserv. Biol. 13:1124–1139; Viña and Cavalier 1999. Biotropica 31:31–36). Because of this and its narrow distributional range (< 20,000 km^2), *Cochranella savagei* is listed as "vulnerable" by the International Union for Conservation of Nature and Natural Resources (Bolivar et al. 2004. *In* IUCN 2006. IUCN Red List of Threatened Species. www.iucnredlist.org). A knowledge of the natural history of species such as *C. savagei* will be important in the implementation of management strategies for conservation.

DENDROPSOPHUS ELEGANS (Elegant Forest Treefrog). **PREDATION.** Amphibians and reptiles are commonly preyed upon by spiders (Neill 1948. Herpetologica 4:158). In Brazil, the spider *Ancylometes* spp. (Araneae, Pisauridae) has been reported as an anuran predator (Bernarde et al. 1999. Biociências 7:199–203). Herein, we report predation of an adult *Dendropsophus elegans* in São José do Barreiro, São Paulo, southeastern Brazil (22°38'S, 44°34'W; 502 m elev.). A large number of *D. elegans* perched on branches and leaves of emergent vegetation were observed calling along the edge of a small perennial pool (ca. 6 × 12 m). On 13 Oct 2006 at 2100 h, one of us (HS) observed an adult male *D. elegans* (30 mm SVL) on grass leaves that was being eaten by the psaurid spider, *Ancylometes* spp. (21 mm cephalothorax and abdomen length). The spider was standing over the prey with its chelicerae fixed in the tree frog's head. After two hours a large area of necrotic tissue was visible around the bite. The frog was dead when the spider was collected.

Voucher specimens of the spider and frog are in the Instituto Butantan and Coleção Jorge Jim,UNESP, Botucatu, SP. We thank A. D. Brescovit for spider identification and FAPESP for financial support.

DENDROPSOPHUS SARAYACUENSIS (Shreve's Sarayacu Treefrog). **PREDATION**. Predatory events in nature are rarely observed and published (Martins et al. 1993. Amphibia-Reptilia 4:273–296). However, these events are common and records in the literature are generally based on fortuitous observations of single events involving spiders and anurans (e.g., Formanowicz et al. 1981. Herpetologica 37:125–129; review in Menin et al. 2005. Phyllomedusa 4:39–47). Herein we report the predation of a juvenile *D. sarayacuensis* (15 mm SVL) by the spider, *Ancylometes rufus* (male; 9.32 mm cephalotorax + abdomen length). The observations were made in the "terra firme" forest, Municipality of Castanho, State of Amazonas, northern Brazil (03°60'66.5"S, 60°19'78.4"W).

On 15 May 2005 at ca. 1135h a juvenile *D. sarayacuensis* was observed in the grass moving in the direction of the spider and its web. When the frog was near to the spider, the frog was attacked. The spider caught and immobilized the frog, inserting its chelicerae in the abdominal region. The spider held the treefrog for 5 min until it was dead. Despite the fact that spiders commonly prey on amphibians, the impact of this predation on populations of amphibians is unknown (Menin et al. 2005, *op. cit*.).

We are grateful to A. P. Lima and C. S. Azevedo for identification of the treefrog and spider; M. Menin for suggestions on the manuscript; M. Davis for the English review; and CNPq for scholarships to DJR and CAPES to RA for financial support.

HYALINOBATRACHIUM PULVERATUM (Chiriqui Glass Frog). **PREDATION.** *Hyalinobatrachium pulveratum* is found in

lotic habitats from Honduras to Colombia (Savage 2002. The Amphibians and Reptiles of Costa Rica. University of Chicago Press, Chicago, Illinois, 934 pp.). Little is known of its population biology, although Hawley (2006. J. Trop. Ecol. 22:731–734) reported embryonic development and mortality in a Costa Rican population. Here we report observations demonstrating that ants of the genus *Crematogaster* (Myrmicianae) are an additional predator capable of causing complete clutch mortality of *H. pulveratum* during early (immobile) and later (mobile) embryonic stages. All observations were made along the Quebrada Bilingual (8°26'N, 83°22'W) in the Osa Peninsula, Costa Rica.

FIG. 1. Top: Clutch of *Hyalinobatrachium pulveratum* embryos being attacked by *Crematogaster* ants on 5 August 2006. Bottom: Ants transporting embryos away from the clutch. Photos by TJH.

On 1 May 2005, TJH observed *Crematogaster* ants attacking a desiccated *H. pulveratum* clutch in an early developmental stage. Ants were extracting embryos from the thin layer of jelly. Two days later no eggs were found on the leaf.

On 5 Aug 2006, TJH and JC observed ants extracting, transporting, and consuming embryos from a desiccated clutch (ca. developmental stage 21; Gosner 1960. Herpetologica 16:203–210) (Fig. 1) on an *Inga* leaf. At 1445 h, four embryos were observed on the leaf separate from the clutch, two were intact (with body and tail), but only the body remained of the other two. During 55 minutes of observation (1530–1625 h) 15 ants were observed interacting with embryos. At 1530 h, we observed an ant transporting one embryo 3–5 cm from the clutch. Later, three ants moved this embryo about 9 cm from the clutch to the underside of the leaf. They pulled at the body and yolk region using their mandibles and legs, apparently consuming portions of the embryo. Another embryo was ca. 3–5 cm from the clutch, being consumed by three ants.

During the observation, ants attempted to extract one embryo from the clutch. One ant appeared to be chewing through the clutch jelly and trying to grasp a living embryo by its tail. Ants repeatedly arrived at the clutch, tried to extract the embryo, and then departed. Often their attempts were not successful, suggesting that it is difficult to extract embryos. Embryos occasionally moved, but were presumably unable to extract themselves from the jelly and hatch early. The tough, elastic nature of the dehydrated jelly may have made attempts to hatch early unsuccessful.

The following day (6 Aug) at 945 h more ants (30+ individuals) were observed and few embryos remained, but all were living. On 7 Aug, no embryos remained.

Crematogaster ants are known to receive sugar rewards from foliar nectaries on *Inga* in exchange for protecting the new leaves from herbivory (Koptur 1984. Ecology 65:1787–1793). *Hyalinobatrachium pulveratum* clutches are often found on *Inga* leaves but we suspect that the ants are capable of attacking the clutches only when the jelly layer is thin due to desiccation. The observations indicate that *Crematogaster* ants are capable of causing total clutch failure under these conditions.

We thank P. and G. Sanchez for permission to work on their property and support in the form of EPA-GRO and Evergreen Fellowships to TJH. We are grateful to J. Longino for confirming the identification of the ants, and to J. Lee and D. Matlaga for reviewing this manuscript.

HYLA PICADOI (NCN)**. VOCALIZATIONS**. *Hyla picadoi* is a small to medium sized neotropical hylid frog that inhabits bromeliads attached to the trunks and branches of the humid montane forest canopy of Costa Rica and Panama (Savage 2002. The Amphibians of Costa Rica: a Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.; Duellman 2001. The Hylid Frogs of Middle America.

TABLE 1. Call attributes (mean ± standard deviation) of the bromeliad dwelling *Hyla picadoi* from western Panama. Recorded *in situ* under weather conditions of intermittent rain, 86.1% relative humidity and 16.4°C air temperature.

call type	calls	dominant frequency (Hz)	total call lengths (s)	pulse length (s)	click series length (s)	total clicks	single clicks	double clicks	triple clicks
typical	N = 16	2035.19 ± 103.32	6.30 ± 0.88	1.53 ± 0.24	4.77 ± 0.86	12.75 ± 3.38	2.13 ± 1.41	4.38 ± 1.41	0.63 ± 0.81
short	N = 3	2067 ± 84.50	3.939 ± 0.75	0.24 ± 0.42	3.70 ± 0.96	12.67 ± 2.31	4.67 ± 2.31	2.00 ± 1.00	1.33 ± 1.15

2nd ed. Society for the Study of Amphibians and Reptiles. 1180 pp.). On 26 May 2006, 2100–2130 h, we made *in situ* recordings of this species in the cloud forests of the Los Quetzales Lodge Preserve (8°52'35"N, 82°32'50"W, 2200 m elev.), a private land holding adjacent to Parque Nacional Volcan Barú. Weather conditions consisted of bouts of intermittent rain, 86.1% relative humidity and 16.4°C air temperature. We recorded *H. picadoi* in the field at 44.1 kHz sampling rate using a Tascam DA-P1 digital audio tape recorder via an Audio-Technica 835b semi-directional microphone. Recordings have been deposited and catalogued (BLB-32346) in the archives of the Borror Laboratory of Bioacoustics at The Ohio State University.

Calls originated from at least five distinct locales within the forest canopy at varying distance and direction from the authors. Of these, 19 calls from three individuals (presumably male) were recorded under high quality conditions with low background noise. Recordings were made at distances ranging from 3 to 15 m from source animals. Vocalizations were analyzed and graphically constructed using Raven Pro v.1.2.1 interactive sound analysis software from Cornell University Bioacoustic Research Program. No morphometric measurements were possible on recorded subjects as they were out of reach of capture. Confirmation of this vocalization as being that of *H. picadoi* was established through visual identification by EDL at a date prior to obtaining digital recordings.

A typical vocalization for *H. picadoi* was initiated by a single, amplitude modulated pulsed segment, followed by a variable combination of single, double and/or triple clicks in series (Fig. 1 and Table 1). Typical calls sounded like "creeeeeek crik crik crikek crikek crikek crikek crikekek." Calls between neighboring males generally did not overlap. However, during bouts of intense calling activity, the pulsed initial segment was reduced or eliminated (N = 3), truncating the overall length of vocalization (Fig. 2 and Table 1). This observation is interesting and may indicate differ-

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). **SAUROPHAGY**. On 11 Nov 2006, a subadult Cuban Treefrog (SVL 35 mm; 1.6 g; UF 150247) was observed consuming a subadult female Green Anole (*Anolis carolinensis*; SVL 33 mm; 0.8 g; UF 150248) among a coiled garden hose at 8711 W. Knights Griffin Road in Plant City, Florida (28°04'45.2"N, 82°14'75.1"W). The frog was photographed, allowed to finish consuming the lizard, collected, measured, weighed, frozen, then dissected to extract, identify, measure, and weigh the lizard; both were then preserved in formalin. One large male, a large female, and two other subadult Green Anoles were present among the coiled garden hose at the time of this observation. Green Anoles, Brown Anoles (*Anolis sagrei*), and Cuban Treefrogs are abundant at this location and regularly utilize this and other garden hose, water tank, and other ruderal sites, especially during winter months. The Cuban Treefrog is known to consume many native anurans (Meshaka 2001. The Cuban Treefrog in Florida, Univ. Press Florida; Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publishing, Malabar, Florida), at least one introduced lizard (*Anolis sagrei*; Meshaka 2001, *op. cit.*), and even native snakes (Maskell et al. 2003. Herpetol. Rev. 34:137), but this is the first record of the native *A. carolinensis* in its diet.

FIG. 1. Juvenile Cuban Treefrog in the process of consuming a similar-sized Green Anole.

PHYSALAEMUS FISCHERI (Fischers Dwarf Frog). **MALE-MALE AGGRESSION**. Male-male combat has been described in two species of the genus *Physalaemus*, *P. cuvieri* (Barreto and Andrade 1995. Amphibia-Reptilia 16:67–76) and *P. centralis* (Aguirre 1998. Herpetol. Rev. 29:165), and in the closely related *Engystomops pustulosus* (Ryan 1985. The Túngara Frog: A Study in Sexual Selection and Communication. University of Chicago Press, Chicago, Illinois). Herein I report a field observation of male-male combat in *Physalaemus fischeri* (= *enesefae*), observed in 1997 at Fundo Pecuario Masaguaral (8°34'N, 67°35' W), Guárico State in the Venezuelan Central Llanos. *Physalaemus fischeri* males call from shallow water amidst vegetation. Males occupy the same site throughout the night and for several consecutive nights, although they do not defend territories (Tárano and Herrera 2002. Ethology 108:1–14). One night, while recording male calls in the field, I noticed an unusual call pattern and pitch shift from a nearby male. Initially, calls were typical (Tárano 2001. Copeia 2001:1064–1072) but suddenly the male's call pitch slightly increased, its call length shortened and the male stopped calling. Then I observed two males engaged in body combat. The two frogs, the caller and a presumed intruder, kicked, jabbed each other, and rolled on the ground. The combat lasted less than one minute. Afterwards, one male jumped away while the other remained in the vicinity of the original calling site. The former returned after a few seconds and both males resumed fighting for a few more seconds. The combat ended when one male left the site. I could not determine whether the 'winner' was the resident male or the intruder. The remaining male did not resume calling within the next 5 minutes. Displacement of amplectant males has not been observed in *P. fischeri* and potential satellite behavior has been observed rarely (Tárano and Herrera 2002, *op. cit.*). In addition, calling males can be close together in dense choruses (10 cm apart), or during high activity nights indicating that males are quite tolerant of other males. Proximate causes of the observed aggression could not be determined.

PHYLLOMEDUSA AYEAYE (Reticulate Leaf Frog). **HABITAT AND CONSERVATION.** *Phyllomedusa ayeaye* is listed as critically endangered (Caramaschi and Gonçalves da Cruz 2004. 2006 IUCN Red List of Threatened Species. <www.iucnredlist.org>. 09 Feb 2007). This species is known from a few sites within the Poços de Caldas Plateau, state of Minas Gerais, Brazil (21°47'S, 46°33'W). The type specimens were collected around artificial, water-filled trenches (Lutz 1966. Copeia 1966[2]:236–240). Cardoso et al. (1989. Rev. Brasil. Biol. 49[1]:241–249) reported males calling around a permanent, water-filled artificial pit. In 1988 AAG found tadpoles in this same pit. On 18 Nov 2006, at the type locality, we found a male *P. ayeaye* calling perched on vegetation bordering a trench (ca. 1 m wide, 2 m deep) where rainwater had accumulated ca. 0.4 m deep. The trench is bordered by scattered small trees (< 4 m tall) and shrubs. It runs down a hill covered by natural altitudinal fields (ca. 1300 m asl) used for extensive cattle farming. *Leptodactylus cunicularius* (Sazima and Bokermann 1978. Rev. Brasil. Biol. 38:904) was also calling along the trench. This site is less than 10 km from the site described by Cardoso et al. (1989 *op. cit*.). As far as we know, this observation of *P. ayeaye* in nature is the first reported in the last 26 years. The Poços de Caldas Plateau is currently undergoing extensive human alteration by expansion of *Eucalyptus* plantations that eliminate natural grasslands. Considering the large number of endemic frogs in the region (Giaretta and Sazima 1993. Rev. Brasil Biol. 53[1]:13–19; Vasconcelos and Giaretta 2003 Rev. Esp. Herpetol. 17:21–27), immediate plans to reverse this trend are necessary. Our data is important because it indicates that *P. ayeaye* also uses deep ponds in open areas and that not only the forest habitat but also the natural altitude fields need to be protected.

PLEURODEMA CINEREUM (Puna's Four-eyed Frog). **COMMUNAL OVIPOSITION.** Communal oviposition has been recorded in several species of Leptodactylid frogs in the genera *Pleurodema* and *Physalaemus* (Zina 2006. Amphibia-Reptilia 27:148–150). Here we describe communal oviposition from a population of *Pleurodema cinereum* in the urban area of Copacabana (16°09'58"S, 69°05'09"W), 700 m from the coast of Titicaca Lake, La Paz Dept., Bolivia. Titicaca Lake, 3850 m elev., is located in the Puna of the Bolivian Altiplano. The wet season extends from December through March, with an average of 1000 mm rainfall, but with 50% annual variation. The rains are mild and constant almost every day. These observations occurred on 31 Dec 2005 in two temporary pools located in an untilled field in the town of Copacabana. The two pools had a surface area of ca. 105 m^2 and ca. 35 m^2, with a mean depth of 15 cm. They were covered by some aquatic vegetation, principally Juncaceae. Explosive choruses of *P. cinereum* were found after several days of mild afternoon rainfalls. Observations began at 1500 h (Water = 10°C; Air = 7.5°C). Two different communal oviposition sites were located, with 9 amplecting pairs in the larger and 6 in the other. The release of eggs and the jelly beating were directed toward the center of the ellipse, and that produced a large foam mass. The foam of the 9 amplecting pairs measured 28 cm × 12 cm, and the other 20 cm × 11 cm. Only males were observed to participate in the jelly beating and building of the foam nest. This is similar to observations reported by Fernandez and Fernandez (1921. An. Soc. Cient. Arg. 91:97–140).

We found an additional 11 completed communal nests and 4 that, because of their small size (7 cm diameter), were probably built by single pairs in amplexus. All nests were within the more heavily vegetated areas that provided better attachment and protection. During the period of observation, we found ca. 40 calling males, 16 close to the communal oviposition sites. We also found 10 unmated females and 9 amplecting pairs close to each other that had not begun construction of their foam nest. The calling males and all of the amplecting pairs were in the shallowest parts of the ponds, 5–7 cm deep.

As suggested by Hödl (1990. Copeia 1990:547–554), communal oviposition could result from the scarcity of adequate sites for the construction of the foam nest, or else represent a strategy against

FIG. 1. Communal oviposition in *Pleurodema cinereum* found near the coast of Titicaca Lake, Dpto. of La Paz, Bolivia, on 31 December 2005. The arrow shows an unmated male.

desiccation. In this particular case both hypotheses appear feasible if we consider Puna's unfavorable weather, the conditions of the ponds, and the explosive reproductive behavior of *P. cinereum*.

We thank D. Ferraro, D. Baldo, C. Morgan, J. M. Barnett, and J. Zina for their contributions.

Submitted by **M. GABRIELA AGOSTINI** (e-mail: gagostini@quimica.unlp.edu.ar), **RODRIGO CAJADE**, and **IGNACIO ROESLER**, CIMA Dpto. de Química, Facultad de Ciencias Exactas, UNLP.

PSEUDACRIS HYPOCHONDRIACA (San Lucan Chorus Frog). **REPRODUCTION**. Much of the information on reproduction in this species is available under an earlier name, *Hyla regilla* (Schaub and Larsen 1978. Herpetologica 34:409–416) and little is known of populations in Mexico. In Baja California Sur, *P. hypochondriaca* breeds during wetter months; in the Cape Region there are reports of calling males and amplexus from January through October (Grismer 2002. Amphibians and Reptiles of Baja California: Including Its Pacific Islands and the Islands in the Sea of Cortez. University of California Press, Berkeley. 399 pp.).

On 11 Dec 2006, 2120 h, we found an adult female (40.1 mm SVL, 8.9 g) *P. hypochondriaca* with evidence of eggs inside her body. At 0900 h the next day the frog was measured, weighed, and marked with VIE (Visible Implant Elastomer). At 1500 h she was released at the point of capture, a small, shallow (4 sq. m, 10 cm deep) temporary pond in Cañón de Santa Rita, Sierra de la Laguna, southern Baja California Sur, México (23°28.28'N, 109°48.5'W; elev. 267 m). At 1600 h we found the same female in amplexus with a male (33.4 mm SVL, 4.2 g) and two hours later the amplexus finished. The female deposited 6 egg massess (total of 82 eggs), which were attached to aquatic vegetation at 5 cm depth. After amplexus, the female lost 2.9 g (32.6%)of her mass. This information contributes to the knowledge of reproduction in *P. hypochondriaca* females in the southernmost part of their distribution.

We thank Abelino Cota for assistance with fieldwork.

RANA BOYLII (Foothill Yellow-legged Frog). **PREDATION.** On 10 May 1996, an adult female Sacramento Pike Minnow (*Ptychocheilus grandis*; 451 mm TL, 950 g) was collected from the margin of the Eel River near Holmes, Humboldt Co. California, USA. Stomach analysis revealed an adult Foothill Yellow-legged Frog, *Rana boylii* (70 mm SUL), one complete *R. boylii* egg mass, and five Threespine Stickleback (*Gasterosteus aculeatus*). The frog and egg mass (31.49 g, combined weight) were undigested suggesting recent ingestion (< 1 h). With few exceptions, previous literature does not describe amphibians in the diet of *P. grandis* (Brown 1990. Southwest. Nat. 35:249–260; Taft and Murphy 1950. California Fish Game 36:147–164).

In California, *R. boylii*, a state species of special concern, is rare or absent in habitats where introduced aquatic predators are present (Jennings and Hayes 1994. Amphibian and Reptile Species of Special Concern in California. California Dept. Fish and Game, Rancho Cordova, California. 255 pp.). *Rana boylii* has been extirpated from much of its historical range in areas where it was sympatric with *P. grandis*, primarily the Central Valley and central Coast Ranges. The majority of extant *R. boylii* populations are outside the present range of *P. grandis*, although they are sympatric in the Eel River.

In 1979, *P. grandis*, a California endemic, was illegally introduced into the Eel River drainage. By 1986 it had successfully colonized ca. 200 km of river (Brown and Moyle 1997. Environ. Biol. Fishes 49[3]:271–291). During a diet analysis of this *P. grandis* population, amphibians were found in 42 of 345 individuals. Brown and Moyle (1997, *op. cit.*) concluded that in the Rice Fork of the Eel River, frogs and tadpoles are an important part of the diet. Although we do not believe *P. grandis* is a primary threat to *R. boylii*, it is of concern that an egg mass as well as an adult frog were taken. Monitoring of the interaction between these species would be valuable.

RANA CAPITO (Gopher Frog). **REFUGE DURING FIRE.** Most animals have adaptive behaviors that help them escape fire, but little is known about how amphibians survive fires in fire-maintained ecosystems. During a radio-telemetry study of *Rana capito* in the Ocala National Forest, Marion County, Florida, USA, the U.S. Forest Service conducted a prescribed fire on 20 July 2006 as a normal management activity to maintain suitable habitat for *R. capito* and other species that occur in the longleaf pine, *Pinus palustris*, ecosystem. Two newly metamorphosed juveniles with attached transmitters were present in the burn area during this time. They were captured at drift fences surrounding ephemeral ponds and outfitted with external transmitters at ca. 1100 h on 19 July 2006. Immediately following transmitter attachment they were released near the capture site. We located the frogs immediately post-fire at ca. 2000 h on 20 July 2006. One frog moved 71 m from the drift fence into an abandoned burrow excavated by an adult Gopher Tortoise, *Gopherus polyphemus*. The second frog moved 43 m from the drift fence into an unburned patch of Wiregrass, *Aristida stricta*. Because we did not locate these frogs immediately before the fire, we do not know whether they moved to refuges in response to the fire or sometime during the previous day before the fire.

These observations indicate that *R. capito* is able to survive fires in underground refuges and in areas that do not burn when the fire passes. There was no evidence of mortality, as we might expect for a species that evolved in a fire-maintained ecosystem. Richter et al. (J. Herpetol. 35:316–321) reported no mortality of three adult Dusky Gopher Frog, *R. sevosa*, during a prescribed fire, also suggesting that *R. capito* are not highly vulnerable to fire. These observations highlight the importance of heterogeneous fire, which allows animals to take shelter in unburned areas when no other refugia are available.

The Florida Fish and Wildlife Conservation Commission provided funding for the radio-telemetry study on *R. capito*.

JOHNSON**, Department of Wildlife Ecology and Conservation, Univ. Florida-IFAS Plant City Campus, Plant City, Florida 33563, USA (e-mail: tadpole@ufl.edu).

RANA CATESBEIANA (American Bullfrog). **DIET.** On 2 January 2006 we observed *Rana catesbeiana* ingesting a native Haitian tree frog, *Osteopilus dominicensis*. The incident took place in an area of canal runoff near Hospital Albert Schweitzer in Deschapelle, Haiti at 2130 h. In Haiti, *R. catesbeiana* is an exotic, invasive species (Schwartz and Henderson 1988. Milwaukee Publ. Mus. Contr. Biol. Geol. No. 74, 264 pp.). *Rana catesbeiana* were first reported in Haiti in 2002 by the Invasive Species Specialist Group (ISSG). Surprisingly, *R. catesbeiana* is not listed as an invasive species threat in the Caribbean (Kairo and Ali 2003. Rept. to the Nature Conservancy. CAB International, Trinidad and Tobago). In other areas, introduced *R. catesbeiana* may be responsible for significant levels of predation on native anurans and other aquatic herpetofauna (Rosen and Schwalbe 1995. *In* Laroe et al. [eds.], U.S. Dept Interior, Natl. Biol. Serv., Washington, D.C. 530 pp.). Until recently, the range overlap of *R. catesbeiana* with any member of the genus *Osteopilus* has been limited to the Caribbean. However, the latest northward expansion of *O. septentrionalis* in Florida, USA has brought these two species together (P. Moler, pers. comm.). Thus, opportunities for such a predatory observation have been limited and this observation represents the first documented case of *R. catesbeiana* preying on a member of the genus *Osteopilus*. The *R. catesbeiana* appeared to foam at the mouth while ingesting the *O. dominicensis*, probably due to the toxic skin secretions, but this reaction did not appear to deter the act of ingestion. Several male and female *R. catesbeiana* were encountered at this site suggesting establishment in the immediate area.

We thank Becky and Ted Crosby of the Crosby Fund for Haitian Education for giving us the opportunity to visit Haiti.

RANA CATESBEIANA (American Bullfrog). **PREY.** *Rana catesbeiana* is known to be an efficient predator of small vertebrates. Although amphibians can make up a large part of the diet, predation on snakes has been noted by several authors. Here we report *Liophis p. poecilogyrus* as prey of a female *R. catesbeiana* (SVL 109.2 mm). The frog was collected by S. L. Lima on 17 Aug 1983, in the municipality of Coimbra, Minas Gerais State, southeastern Brazil. The frog was fixed opened to show the whole prey (Fig. 1). The snake (TL 336.1 mm) was well preserved and its tail was hanging out of the frog's mouth, suggesting that it was swallowed just before collection. *Liophis poecilogyrus* is a terrestrial snake that feeds on anurans. It is well distributed over South America, with diurnal and nocturnal habits.

Rana catesbeiana is a nonnative species in Brazil, where it was introduced in the 1930s for commercial harvest. Because of poor management practices and high survival of individuals in wild habitats, this species established feral populations in many regions of the country. The voucher specimens currently are deposited at Museu de Zoologia João Moojen, Universidade Federal de Viçosa, Viçosa, Minas Gerais State, Brazil (*R. catesbeiana* MZUFV 202, *Liophis p. poecilogyrus* MZUFV 1380).

We thank Jorge A. Dergam for his comments on this note.

Submitted by **EMANUEL T. DA SILVA, HENRIQUE C. COSTA,** and **RENATO N. FEIO**, Departamento de Biologia Animal, Universidade Federal de Viçosa, 36571-000 Viçosa, Minas Gerais State, Brazil (e-mail: etsbio@yahoo.com.br).

RANA SPHENOCEPHALA (Southern Leopard Frog) and ***SCAPHIOPHUS HOLBROOKII*** (Eastern Spadefoot). **REPRODUCTIVE BEHAVIOR.** Southern Leopard Frogs are most active in the winter and spring, and Eastern Spadefoots are explosive breeders stimulated by heavy rainfall events (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians in Florida. Part III: The Amphibians. Windward Publ. Co., Miami. 191 pp.). In Florida, both species can be found breeding in the same wetland, especially in the fall or winter months. Here I report a case of inter-species amplexus following a heavy rain in early February.

From 1–2 February 2007, ca. 7 cm of rain fell in Micanopy, Alachua County, Florida, USA. On the night of 2 February a chorus composed of *Pseudacris crucifer* (Spring Peeper), *P. ocularis* (Little Grass Frog), *Rana grylio* (Pig Frog), and *R. sphenocephala* was heard in an ephemeral wetland ca. 6 km E of Micanopy. *Scaphiopus holbrookii* were not heard at this location, although large numbers were heard and seen in nearby wetlands. Several *R. sphenocephala* were observed in amplexus within the wetland, including one male (48.5 ± 0.1 mm SVL, 9.5 ± 0.5 g) that had amplexed a male *S. holbrookii* (46.1 ± 0.1 mm SVL, 7.7 ± 0.5 g). The pair was found floating near emergent vegetation in 0.5–0.75 m of water at ca. 2130 h. When approached, the *R. sphenocephala* attempted to escape, but I easily captured the pair and relocated them to shallow water for a photograph.

Aside from missed feeding and reproductive opportunities, the cost of inter-species amplexus may include increased predation risks. Encountered pairs of amplexed *R. sphenocephala* attempted escape by swimming together. The *S. holbrookii* amplexed by the *R. sphenocephala* remained motionless throughout the encounter. Several active *Agkistrodon piscivorus* (Cottonmouth) were observed in the wetland.

FIG. 1. Male *Rana sphenocephala* in amplexus with a male *Scaphiopus holbrooki*, from north-central Florida on 2 February 2007.

SMILISCA SORDIDA (Drab Tree Frog). **PREDATION**. Spiders are well known predators of frogs (Brasileiro and Oyamaguchi 2006. Herpetol. Rev. 37:451; da Costa et al. 2006. Herpetol. Rev. 37:337–338; Formanowicz et al. 1981. Herpetologica 37:125–129; Prado and Borgo 2003. Herpetol. Rev. 34:238–239). Herein I report a case of spider predation on *Smilisca sordida*. On 22 Jan 2005 at 1955 h, in the Refugio de Vida Silvestre, Golfito (Costa Rica, Puntarenas Province, 08°39'N, 83°11'W, ca. 5 m elev.) I observed an adult male *S. sordida* being caught and bitten in the chest by the spider *Ancylometes bogotensis* (Fig. 1). The frog was 41 mm SVL, whereas the combined length of prosoma and opisthosoma of the spider was 21 mm. The frog struggled and tried in vain to get free by grabbing the spider with its forelegs but stopped moving and was apparently dead after about 90 sec. After an additional 4 min the spider carried the dead frog into its hide and immediately started to feed.

I thank the University of Costa Rica for support, and G. Dehling, M. Dehling, W. Lapinski, and T. Sandner for suggestions.

FIG. 1. Predation on adult male *Smilisca sordida* (SVL = 41 mm) by *Ancylometes bogotensis* (combined length of prosoma + opisthosoma = 21 mm).

GYMNOPHIONA

CAECILIA THOMPSONI (Thompson's Caecilian). **MAXIMUM BODY SIZE**. *Caecilia thompsoni* occurs in northern South America, specifically in the Magdalena River Valley, Colombia. Previously, a specimen 1550 mm total length was reported as the largest caecilian known. The specimen was collected on the Riomanso Private Natural Reserve, La Dorada municipality, Caldas Department (Acosta et al. 2006. Rev. Acad. Colomb. Cienc. 30[115]:291–303). Here, I report a new maximum body size for *Caecilia thompsoni* from a specimen collected in Victoria municipality (southwestern of the Riomanso Reserve).

On 19 Jan 2006, at 1550 h I collected an adult male *C. thompsoni* on the east margin of Casanguillas stream in the vereda El Llano, Victoria municipality, Caldas Department (5°19'38.8"W,

74°50'45.8"N, 328 m elev.). The Casanguillas stream is located in a pasture with a narrow strip of riparian vegetation (3–5 m wide). This specimen was 1767 mm total length, exceeding the previous record of maximum body size for this species by 217 mm. This specimen increases the range of primary annuli for the species from 240 to 253 (Lynch 1999. Rev. Acad. Colomb. Cienc. 23 [spec. suplem.]:317–337). This specimen is the longest caecilian reported.

The specimen is deposited in the Museo de Herpetología Universidad de Antioquia (MHUA 4432) and was collected under environmental authority permits obtained by Instituto De Estudios Ambientales (IDEA) of Universidad Nacional de Colombia Sede Medellín.

Submitted by **JUAN CAMILO ARREDONDO SALGAR** jcas36@gmail.com Museo de Herpetología Universidad de Antioquia, Instituto de Biología, Universidad de Antioquia, AA.1226 Medellín, Colombia.

CROCODYLIA

CROCODYLUS INTERMEDIUS (Orinoco Crocodile). **JUVENILE FEEDING.** *Crocodylus intermedius,* one of the most critically endangered species of crocodilians (Rodríguez and Rojas 2003. Libro Rojo de la Fauna Venezolana, IUCN. 2nd ed., Fundación Polar/PROVITA, Caracas. 472 pp.), inhabiting the Orinoco River Basin in Venezuela, is the focus of captive breeding and habitat protection policies (Thorbjarnarson 1988. Proc. World Conf. Breeding Endangered Species Captivity 5:307–314). Few data exist on the feeding behavior of juvenile crocodiles (*C. acutus* [Thorbjarnarson 1989. *In* Hall [ed.], Crocodiles: Their Ecology, Management and Conservation, pp. 228–258. Special Publication of the Crocodile Specialist Group IUCN/SSC. Gland, Switzerland]; *C. johnstoni* [Webb et al. 1982. Aust. J. Zool. 30:877–899]; *C. niloticus* [Games 1990. *In* Proc. Ninth Working Meeting Crocodile Specialist Group. Vol. 1, pp. 251–267. IUCN. Gland, Switzerland]; *C. porosus* [Taylor 1979. Aust. Wildl. Res. 6:347–359; Davenport et al. 1990. J. Zool. London 220:569–592]), but no published data exist on the feeding behavior of juvenile *C. intermedius*. Hence, here I report an observation of juvenile *C. intermedius* feeding.

I made the observation at Fundo Pecuario Masaguaral, a cattle ranch with a crocodile farm (Blohm 1982. *In* Proc. Fifth Working Meeting IUCN/SSC Crocodile Specialist Group, pp. 267–285. Gland, Switzerland) in the State of Guárico in the Central Llanos of Venezuela (8°34'N, 67°35'W; elev. 60–75 m). The Central Llanos are lowlands (below 75 m elevation) with a well-defined wet season (May–Nov) dominated by open grasslands interspersed with deciduous forests (Troth 1979. *In* J. Eisenberg [ed.], Vertebrate Ecology in the Northern Neotropics, pp.17–30. Smithsonian Inst. Press, Washington, DC). At 2000 h (at night), I encountered a juvenile *C. intermedius* (ca. 2.5 months old, 38 cm total length) holding an adult dead male *Bufo granulosus* (ca. 4.5 cm SVL) with its jaws in a water-filled truck track ca. 9 cm deep on an unpaved road. The juvenile *C. intermedius* was in the water, with only its head above the surface, holding the dead toad with its jaws, which first I noticed when I captured the juvenile. The toad was flaccid, belly down, head inward, body axis almost parallel to the *C. intermedius*' jaws axis, with only the toad's hind legs being visible outside the *C. intermedius*' jaws. The juvenile *C. intermedius* discarded the toad following capture, presumably because it has been disturbed.

Bufo granulosus males usually call from the ground around puddles (Hoogmoed and Gorzula 1979. Zoologische Mededelingen 54:183–216), so the male *Bufo* may have been vocalizing. The juvenile *C. intermedius* escaped from an enclosure two months before this observation was made but displayed no signs of injury or starvation, suggesting that it was feeding regularly on its own. The juvenile was subsequently returned to its enclosure.

PALEOSUCHUS TRIGONATUS **(**Schneider's Smooth-fronted Caiman**). PREDATION**. Crocodilians, opportunistic predators that eat almost any animal they capture, have diets that vary with age, size, habitat, season, year, and prey availability (Da Silveira and Magnusson 1999. J. Herpetol. 33:181–192; Campos 2004. Herpetol. Review 32:140–141). *Paleosuchus trigonatus*, a small caiman that lives along rainforest streams in Amazonia (Magnusson 1991. J. Herpetol. 25:41–48), is fairly abundant and has a relatively broad distribution. Still, it is rarely observed and data on its foraging behavior are few. Although *P. trigonatus* juveniles and adults are known to consume vertebrates such as small fish, birds, reptiles and mammals (Magnusson et al. 1987. J. Herpetol. 21:85–95), no reports exist of it preying on *Bufo marinus*. Hence, we describe a predation event by *P. trigonatus* on *B. marinus* from northern Brazil.

We made these observations on the night of 28 July 2005 at a small forest lake near the municipality of Curionópolis, State of Pará, Brazil (06°26'2"S, 49°42'59"W, datum: South America 69; elev. 625 m). At 1905 h, we observed an adult (ca 100 cm SVL) *P. trigonatus* that was moving slowly through the water approach the shore and capture an adult *B. marinus* (19 cm SVL) 40 cm above the shoreline. After capturing the toad, the caiman took it to water, but remained at the surface. It then proceeded to elevate its head above the water up to the front arms (ca. 25 cm), and bringing its head down rapidly, slamming its prey on the shoreline margin. This process lasted 20 min. This behavior continued until the caiman had broken off the toad's right leg, and a small piece of the body and the right arm; these were subsequently swallowed. During dismemberment the rest of the *B. marinus*'s body had been thrown onto shore ca. 30 cm from the water margin, where they remained for ca. 10 min. After the caiman had swallowed the first portion of the toad, it retrieved the remains, dragged them back into the water and immediately swallowed them. The entire predation episode took ca. 35 min. After finishing, the *P. trigonatus* sought refuge near some downed branches from a dead tree in the middle of the lake.

TESTUDINES

APALONE SPINIFERA (Spiny Softshell). **PREDATION.** On 2 March 2007, we observed an Eastern Screech Owl (*Otus asio*) in a Wood Duck nest box on the bank of Tippo Bayou on Tallahatchie National Wildlife Refuge, ca. 5 km E Philipp, Tallahatchie County, Mississippi, USA (90°8'35.23"W, 33°45'44.94"N) that had partially eaten a juvenile *Apalone spinifera spinfera* × *A. s. hartwegi* ca. 49 mm in shell diameter. Most hunting by Screech Owls is nocturnal but can be crepuscular, as well as occasionally diurnal (Spendlow 1979. N. Am. Bird Bander 1979:111). They are sit-and-wait hunters that usually make straight-line perch-to-prey strikes (Gehlbach 1994. The Eastern Screech-Owl: Life History, Ecology, and Behavior in Suburbia and the Countryside. Texas A&M Univ. Press, College Station, Texas. 302 pp.). The owl had apparently caught the turtle and brought it back to the Wood Duck box to consume it. When first observed, the owl had eaten the head, three of the legs, and the tail. The remaining leg had been consumed and the shell was desiccated when the box was inspected again on 17 March.

Turtles have not heretofore been reported in the diet of Screech Owls (Gehlbach 1995. *In* A. Poole and F. Gill [eds.], The Birds of North America, No. 165, Academy of Natural Sciences, Philadelphia, and The American Ornithologists' Union, Washington, D.C.; http://bna.birds.cornell.edu/BNA/account/Eastern_Screech-Owl/FOOD_HABITS.html, accessed 23 March 2007). Likewise, Screech Owls have not been reported previously as predators of *A. spinifera* (Carr 1952. Handbook of Turtles. Cornell Univ. Press, Ithaca, New York. 542 pp.; Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 548 pp.; Moler 2007. *In* P. A. Meylan [ed.], Biology and Conservation of Florida Turtles, pp. 173–177. Chelonian Res. Monogr. 3, Chelonian Res. Found., Lunenburg, Massachusetts). This is the first report of *A. spinifera* predation by an Eastern Screech Owl, and this owl as a predator of a freshwater turtle.

EMYS ORBICULARIS (European Pond Turtle). **NEST PREDATION.** On 18 September 2006 a predated nest of *Emys orbicularis* was found on a track near the Arnoia River, Ourense province, northwestrern Spain. Fragments of eggshells were visible within one meter of the hole. A hatchling turtle remained inside the hole, and a small stick was used to get the hatchling out of the nest. Because the nest was positioned between stones, the predator had apparently not been able to reach the bottom of the nest.

Several feces, found near the nest hole and on the track, contained grapes and insects, and presumably were those of a Red Fox (*Vulpes vulpes*). *V. vulpes* is a suspected predator on nests and hatchlings of *E. orbicularis* in Spain (Andreu and Lopez-Jurado 1998. *In* Fauna Iberica. Museo Nacional de Ciencias Naturales, Madrid.; Salvador and Pleguezuelos 2002. Reptiles Españoles. Canseco Eds.). Wild Boars (*Sus scrofa*) and Badgers (*Meles meles*) are also potential predators of nesting female turtles, eggs, and hatchlings, but in this case it seems likely that *V. vulpes* was the nest predator.

GLYPTEMYS INSCULPTA (Wood Turtle). **CARRION-FEEDING**. *Glyptemys insculpta* has been referred to as an opportunistic omnivore (Harding and Bloomer 1979. Bull. New York Herpetol. Soc. 15:9–26). Although carrion is sometimes listed among dietary items for the this species (DeGraaf and Rudis 1983. Amphibians and Reptiles of New England. University of Massachusetts Press, Amherst), observations of carrion-feeding seem to be limited. Surface (1908. Zool. Bull. Div. Zool. Pennsylvania Dept. Agri. 6:105–196) found bird remains in two *G. insculpta* stomachs in Pennsylvania and attributed these to scavenging on dead material. Harding and Bloomer (1979, *ibid*.) and Farrell and Graham (1991. J. Herpetol. 25:1–9) both report the species consuming dead fish. Walde et al. (Can. Field-Nat. 117:377–388) observed Wood Turtles fighting over and eating carrion, including mice, toads (*Bufo americanus*) and fish. On several occasions turtles were observed with feathers in their mouths. Here we report an observation of a *G. insculpta* feeding on the remains of a fresh, road-killed, White-tailed Deer (*Odocoileus virginiana*).

On 30 May 2007, a White-tailed Deer, road-killed the previous day, was field-dressed and disposed of by wildlife technicians off a woods road at North Branch, New Brunswick, Canada (46°10'22"N, 65°15'51"W). The disposal site was about 10 m from the Canaan River, with two small brooks nearby. Approximately 2 h following disposal, two of us (DB and KE) returned to the site and observed an adult female *G. insculpta* (estimated carapace length ca. 180 cm) feeding on the carcass. When first encountered, the turtle had a piece of muscle tissue in its mouth. It continued feeding for about 1 minute while under observation, during which time it was photographed. The turtle was then picked up and briefly examined; when returned to the ground the turtle moved quickly towards the nearest water.

This observation provides additional evidence of the carrion-feeding proclivity of *G. insculpta*. It also suggests that road-killed vertebrates should not be overlooked as a potential source of mortality, where the presence of such might encourage turtles to linger on highways.

GOPHERUS AGASSIZII (Desert Tortoise). **FOOD/MECHANICAL INJURY.** During a long-term growth study on *Gopherus agassizii* growth rates, tortoises have been captured annually since 1964 in Rock Valley, Nevada Test Site, Nye County, Nevada, USA (Medica et al. 1975. Copeia 1975:630–643; Turner et al. 1987.

Copeia 1987:974–979). On two occasions we noted mechanical injury caused by grass seeds, a phenomenon apparently not previously documented. Two tortoises captured 24–25 June 1998 (one subadult and one adult male) exhibited swelling below the eye and posterior to the junction of the upper and lower jaw on both sides of the head. Two additional tortoises (a subadult and an adult female) were observed with the identical condition on 16–17 September 1999. We determined that this was caused by a bolus of plant material (seeds of Red Brome Grass, *Bromus madritensis* ssp. *rubens*) lodged in the junction of the upper and lower jaw on both sides of the head, resulting in an oval distention of the facial integument (Fig. 1). The high precipitation that occurred in Rock Valley during the fall and winter of 1997–1998 (September–March total 304 mm) resulted in the germination and luxuriant growth of this exotic annual grass. Desert Tortoises find Red Brome Grass a palatable food item especially when green (Turner et al. 1984. Copeia1984:811–820; Nagy and Medica 1986. Herpetologica 42:73–92; Esque 1994. MS thesis, Colorado State University, Ft. Collins, Colorado), and will also consume it when it when dry if the tortoise is well hydrated (Nagy and Medica 1986, *op. cit.*)

Between 1998 and 1999, 4 of the 18 (22%) tortoises recaptured in Rock Valley exhibited this condition. The damage inflicted to the jaw by the seeds has persisted for a number of years. In the two adult animals, any sign of mechanical damage (distended flesh in the region impacted by the seeds) disappeared after 3 yr in the female and after 4 yr in the male. After the red brome seeds were removed in two subadult animals, the distended cheek condition continued for 4 yr, and additional seed material was removed each year. Whether the condition is permanent in subadults or might reappear in adult Desert Tortoises is unknown. Three of the tortoises were consumed by predators in 2003, but one subadult tortoise survived through 2004. Its distended mandibular region was still impacted and additional red brome seed material was removed 5 yr after it was first observed with the condition. This bolus of wedged seed material was moist and appeared to be starting to decompose when removed (Fig. 1).

When Red Brome Grass and the related Cheatgrass (*Bromus tectorum*) senesce, the mature seeds have sharp pointed florets that can injure livestock and wildlife species (Crampton 1974. Grasses in California. University of California Press, Berkeley.178 pp.; Currie et al. 1987. J. Range Manag. 40:547–550; McCrary and Bloom 1984. J. Wildl. Manag. 48:1005–1008; Upadhyaya et al. 1986. Can. J. Plant Sci. 66:689–709; Bossard et al. 2000. Invasive Plants of California's Wildlands. University of California Press, Berkeley. 360 pp.). We have also observed a Red Brome seed imbedded its full length within the nostril and in another instance impaled in the corner of the eye of Desert Tortoises. These latter two injuries were observed in Piute Valley, Clark County, Nevada, also during 1998 (the year that Red Brome production was extremely good in Nevada).

We do not know how common injury to Desert Tortoises from Red Brome seeds might be. However, both species of *Bromus* have become widespread throughout the Mojave Desert since the 1960s (Shields et al. 1963. Ecology 44:697–707; Beatley 1966. Ecology 47:548–554; Hunter 1991. Great Basin Nat. 51:176–182) and have increased dramatically in vast areas that have burned in recent years (Brooks and Esque 2002. Chelon. Cons. Biol. 4:330–340). Once invasive annual plants dominate Mojave and Sonoran Desert habitat, an invasive plant-fire regime cycle can be established (Esque et al. 2002. *In* T. R. Van Devender [ed.], The Sonoran Desert Tortoise: Natural History, Biology and Conservation, pp. 312–333. University of Arizona Press and Arizona-Sonora Desert Museum, Tucson, Arizona; Brooks et al. 2004. BioScience 54:677–688). In 2005, over one million acres of Mojave Desert habitat burned in southern Nevada (Young and Clements 2006. Rangelands 28:10–15). Of that burned area ca. 400,000 acres were considered potential *G. agassizii* habitat of which 32,000 acres were within Desert Tortoise critical habitat (Prentice 2006. Desert Tortoise Council Symposium, Tucson, Arizona). The consequent increase in Red Brome Grass might pose both a habitat degradation issue as well as a health risk if tortoises are affected at rates similar to what we observed in Rock Valley.

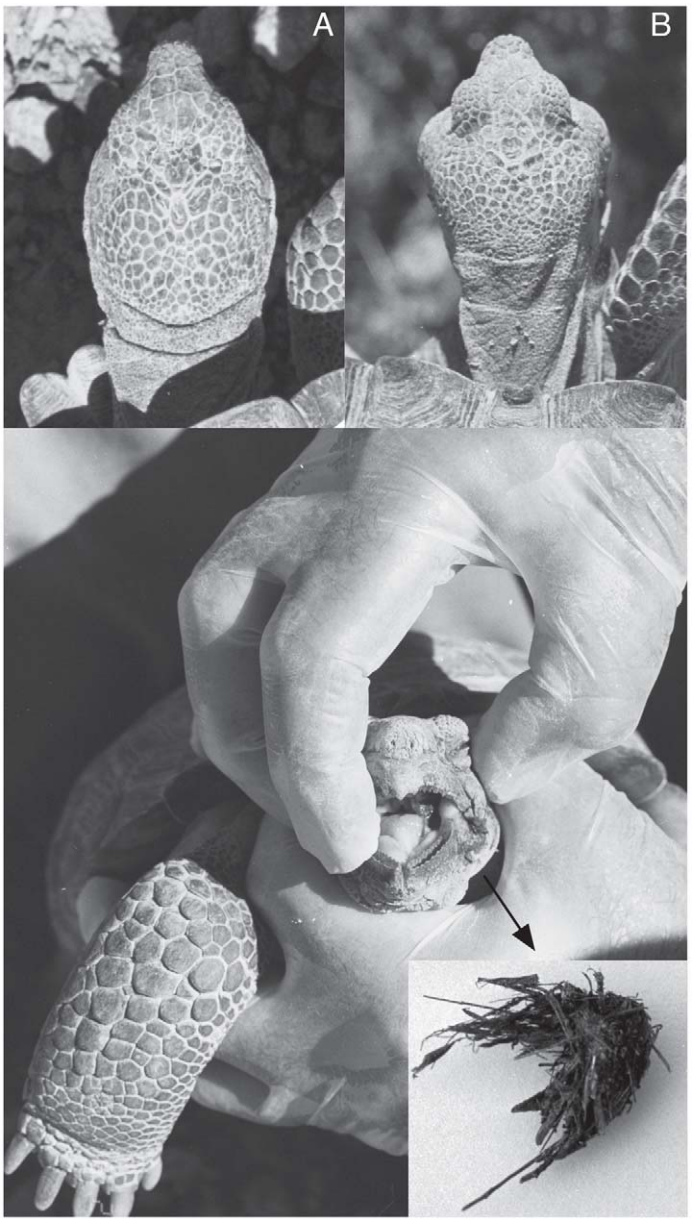

FIG. 1. Upper: Normal head (A) and abnormal head with impacted maxillary region (B). Lower: Impacted maxillary region with inset of the bolus of Red Brome seeds *Bromus madritensis* ssp. *rubens*.

We thank P. S. Corn, K. Nussear, and K. J. Phillips for review-

ing this note. Additionally, we thank the numerous dedicated individuals that have volunteered to assist in the recapture of the Rock Valley Desert Tortoises particularly, J. Burroughs, M. Burroughs, P. Greger. We thank K. Murphy, K. Drake, K. Nolte, and M. Walden for preparing the figures. This study was conducted under Fish and Wildlife Service, U.S. Threatened Species Permit TE 759747, and Nevada Division of Wildlife Permits S-21692, S-24391, and S-28154 issued to (PAM). We gratefully acknowledge the U.S. Department of Energy, National Nuclear Security Administration for continued access to the study area.

NATATOR DEPRESSUS (Flatback Sea Turtle). **HABITAT**. *Natator depressus* are presently believed to occupy habitats with soft substrata during all phases of their lives, almost exclusively in turbid shallow inshore waters (Limpus et al. 1983. Aust. Wildl. Res. 10:557–561; Walker 1990. J. Herpetol. 25:246–248), and to our knowledge have not previously been documented inhabiting hard substrata such as coral reefs, rocky reefs, or mangroves. Here we report a potentially extended range of habitat use that may include rocky reefs and/or mangroves, as surmised by the presence on the carapace of turtles of two species of hard substratum epibionts characteristic of rocky reefs and mangrove forests.

We identified the epibionts attached to the carapace of *N. depressus* while they were ashore nesting on a 2 km long sandy beach near Cape Domett, northern Western Australia (14°48.1'S, 128°24.5'E). Epibionts were present on 28.9% of turtles (N = 142). They consisted of three species of barnacle (Crustracea: Cirrepedia), *Chelonibia testudinaria* (Linnaeus, 1758) (19.0%), *Tubicinella* cf. *cheloniae* Monroe & Limpus, 1979 (4.2%) and *Amphibalanus amphitrite* (Darwin, 1854) (1.4%), and one species of rock oyster (Bivalvia: Ostreidae), *Booneostrea cucullina* (Deshayes, 1836) (7.0%). Thick mud was present on the carapace of 11.3% of turtles, with light mud present on a further 3.5% of turtles.

The barnacle *A. amphitrite* and the oyster are generalists, the former inhabiting the intertidal and shallow subtidal zones, where it lives on many types of natural hard substrata (Stafford and Willan 2007. Is it a Pest? Introduced and Naturalised Marine Animal Species of Torres Strait Northern Australia. Queensland Government Department of Primary Industries and Fisheries, Cairns. 33 pp.) and mangrove pneumatophores (Bayliss 1993. Mar. Biol. 116:251–256), as well as piers and vessel hulls (Stafford and Willan 2007, *op. cit*.). The oyster *B. cucullina* has a similar range of depths and habitat types, including intertidal and shallow subtidal rocky reefs, estuaries and mangrove forests (including mangrove trunks and pneumatophores) (pers. obs). The mud present on the carapaces of the turtles is consistent with such low energy environments.

Both *A. amphitrite* and *B. cucullina* are opportunistic and fast-growing. Therefore, they are easily capable of achieving their observed shell sizes of 16.0 and 17.8 mm maximum diameter, respectively, within the expected 45 days that *N. depressus* are within the nesting area (based on 2.84 nests/season at 16.0 day intervals, Limpus et al. 1984. Aust. Wildl. Res. 11:579–587). The barnacles were sexually mature, but the oysters were not. The presence of these two epibionts on *N. depressus* indicates that the turtles were resident within these habitats for sufficient time for the planktonic larvae of the barnacles and oysters to settle on them, and probably much longer during which time the barnacles had grown to maturity.

These epibionts provide no information as to whether rocky reefs or mangrove forests are utilized only during the inter-nesting period or whether these habitats are used throughout the juvenile and adult phases of the turtles' life cycle. This suggestion of hard substratum residence by *N. depressus* highlights the paucity of information on natural habitats for these turtles in tropical northern Australia and underlines the need for further research.

This research was jointly funded by Charles Darwin University and the Kimberley Region of the Department of Environment and Conservation.

LACERTILIA

AMEIVA AMEIVA (Giant Ameiva). **PREDATION.** *Ameiva ameiva* is broadly distributed throughout South America, ranging from Venezuela and Colombia to Argentina (Vitt and Colli 1994. Can. J. Zool. 72:1986–2008). In the Cerrado Region, it occupies a broad range of habitats but is more abundant in areas with some forest cover (Nogueira 2006. Diversidade e Padrões de Distribuição da Fauna de Lagartos do Cerrado. PhD dissertation, Universidade de São Paulo. São Paulo, Brazil. 295 pp.).

During a diurnal raptor road census at 0950 h on 16 October 2006, we observed predation on *A. ameiva* by the White-tailed Hawk, *Buteo albicaudatus*. It took place at the edge of a small forest fragment, 4 m from an unpaved road on a private farm (22°12'38"S, 47°55'39"W, datum: Corrego Alegre; elev. 760 m) located in the municipality of Brotas, Estado do São Paulo, southeastern Brazil. When first seen, the *B. albicaudatus* was perched on the branch at a height of 2.5 m in a small tree pecking at a lizard held in its claws. Our approaching car caused the hawk to fly away without its prey and perch about 10 m away. The lizard, an adult *A. ameiva* (170 mm SVL, 362 mm tail, 144 g), was dead and had extensive damage right below the head, which was nearly separated from the body.

Buteo albicaudatus is a large (865–1100 g) raptor found in open areas, hill slopes and other open or sparsely wooded country from Texas to Argentinean Patagonia (Ferguson-Lees and Christie 2001. Raptors of the World. Houghton Mifflin Company, New York. 992 pp.). According to Granzinolli and Motta-Junior (Emu, *in press*) lizards represented 0.94% (N = 3296) of all prey consumed and 7.19% (N = 7.2 kg) of biomass ingested by *B. albicaudatus* in Juiz de Fora, southeastern Brazil. However, all *B. albicaudatus* prey lizards found in Juiz de Fora were anguids. Apart from Granzinolli and Motta-Junior (Emu, *in press*), no studies addressing White-

tailed Hawk diet have identified lizards in family level, they just mention "lizards."

Removal of the head from the body may be a common strategy among raptors. Del Royo et al. (1994. Handbook of the Birds of the World. Vol 2: New World Vultures to Guineafowl. Lynx Ediciones. Barcelona. 639 pp.) noted that raptors attack the anterior end of snakes to immobilize the head, presumably reducing risk of being bitten. *Buteo albicaudatus* seems to also use this tactic on lizards. Records of predation on *A. ameiva* exist for snakes (*Crotalus durissus*: Santos and Germano 1996. Herpetol. Rev. 27:143; *Oxybelis fulgidus*: Fischer and Gascon 1996. Herpetol. Rev. 204) and for the Burrowing Owl (*Athene cunicularia*: Tozetti et al. 2005. Herpetol. Rev. 36:443–444). Our observation adds *B. albicaudatus* to its predator set.

The *Ameiva ameiva* voucher was deposited in the Coleção Herpetológica Alphonse Richard Hoge, Instituto Butantãn (IBSP – CRIB 0219). H. Fachin and the staff of Instituto Florestal supported our fieldwork. M. Hayes provided helpful suggestion on a previous version of this note. FAPESP (Fundação de Amparo a Pesquisa do Estado de São Paulo) and FBPN (Fundação o Boticário de Proteção a Natureza) provided financial support. MAMG acknowledges FAPESP for PhD fellowships. This is publication number 30 of the "Ecology of the Cerrados of Itirapina" project.

AMPHIBOLURUS MURICATUS (Jacky Dragon). **PREDATION**. *Amphibolurus muricatus* is a common agamid found primarily in the coastal heathlands of southeastern Australia (Cogger 2000. Reptiles and Amphibians of Australia. Ralph Curtis Publishing, Sanibel Island, Florida. 808 pp.). Despite frequently attaining high local densities, surprisingly little is known about *A. muricatus* ecology. Here, I report several instances of predation on adult *A. muricatus* by the monitor lizard, *Varanus rosenbergi*.

From October 2005 to January 2006, I conducted an extensive field study on *A. muricatus* nesting behavior at The Royal National Park, New South Wales, Australia (34°04'S, 151°05'E, datum: WGS84, elev. 95–105 m). During this study, radio-transmitters were attached to gravid *A. muricatus* throughout the nesting season, and each lizard was relocated hourly until they nested. On two occasions (25 October and 18 November 2005), gravid females were preyed upon by large *V. rosenbergi* within 2 h of release at the study site. These females may have been released in proximity of an unnoticed monitor lizard. On two additional occasions (16 and 31 December 2005), gravid females were preyed upon 2 and 11 days after their respective release dates at the study site. After each predation event, I was able to locate and observe each monitor lizard because the transmitters they swallowed continued to provide a signal. The monitors were not captured, but based on observations of their body sizes, all four predation events may have been the result of at least two different *V. rosenbergi* (~30 cm and ~50 cm SVL).

Additionally, of 15 *A. muricatus* study nests unprotected by chicken wire, two were predated on 25 and 26 October 2005. In both instances, the nests were dug out and all eggs were completely gone only one day after nest construction. Potential predators include small nocturnal marsupials, foxes, cats, or varanid lizards. However, the varanid-like claw marks in the sand around the nest sites, and the fact that both nests were preyed upon during the day strongly suggests varanids were responsible. As I did not observe predation on these nests, the species responsible could have been either *V. rosenbergi* or *V. varius*. Varanids have previously been reported to prey on reptile nests (Blamires 2004. Copeia 2004:370–377) as well as other lizard species (King and Green 1979. Copeia 1979:64–70).

Having to carry a transmitter or female reproductive status, as both factors that can impair mobility or sprint performance (Olsson and Shine 1999. J. Evol. Biol. 13:263–268), could explain these predation events. However, considering that only 4 of out 54 gravid *A. muricatus* with radio-transmitters were preyed upon, predation rates on gravid females may be similar even when they lack transmitters. In general, these observations suggest that *A. muricatus* (and probably their eggs) contribute to the diet of *V. rosenbergi* in this part of their range.

I thank M. Greenlees and R. Shine for comments on this note.

ANISOLEPIS GRILLI (NCN). **REPRODUCTION**. No data exist on reproduction for the enyaliinid anoline, *Anisolepis grilli*. Hence, we provide preliminary data on its reproduction from southern Brazil. We made these observations in the municipality of Vacaria, Rio Grande do Sul state (28°33'S, 50°42'W; elev. ca. 900 m). Vacaria is located in a physiographic region known as the Mountain Top Grasslands in the northeast region of the state. This is the coldest area in the state with mean temperatures ca. 17°C; during winter, temperatures may drop as low as -8°C with frost and occasional snow flurries. Precipitation, 1500–2000 mm annually, is well-distributed seasonally (Boldrini 1997. Bol. Inst. Biocienc. [56]:1–39). Two major vegetation associations exist locally: Brazilian pine (*Araucaria angustifolia*)-dominated forest and savanna (Boldrini, *op. cit*.). Once a month, we visited nine fields in the savanna association with rocky outcroppings and searched for reptiles beneath rocks. We recorded data and collected the eggs from nests of *A. grilli* on 20 May 2005. All specimens collected were deposited in the Scientific Collection of the Herpetology Laboratory of the Universidade Federal do Rio Grande do Sul, Brazil.

During winter 2005, we found two clutches of *A. grilli* under a rock on a transect where all rocks where overturned; this rarely visited place borders a trail with shrubby vegetation (28°16'45.94"S, 50°45'50.03"W, datum: SAD69; elev. 948 m). The depth of the cavity beneath the rock was ca. 25 cm. One clutch (A) had 6 eggs, 3 were no longer viable; the second clutch (B) had seven eggs. Soil temperature was 15.6°C (clutch A) and 16.2°C (clutch B). All eggs had a flexible calcareous shell that was somewhat wrinkled, spherical and averaged ca. 1.5 cm in long axis diameter. One egg was removed from each nest, opened and the embryonic stage recorded. Embryos were deposited in the collection under the numbers DZ 3989 (clutch A) and DZ 3990 (clutch

B). These embryos were, respectively, 23.8 mm and 22.3 mm SVL. We also removed one egg from each nest for incubation in the laboratory; each of the latter eggs was placed in a plastic bag with substrate from the site for transport to the laboratory. We incubated these eggs by locating them 10 cm away from a 40-watt light bulb continuously from 23 May 2005 until they hatched. The individual from clutch A hatched on 30 June 2005 at 27.8 mm SVL, 54.6 mm tail length, and 0.43 g. The individual from clutch B hatched on 7 July 2005 at 28.8 mm SVL, 60.4 mm tail length, and 0.54 g. These individuals were euthanized on 15 July 2005 and were deposited in the aforementioned collection, respectively, under the numbers DZ 3920 and DZ 3921.

These records are of interest because the few data available on *A. grilli* refers to it as arboreal (Lema 1994. Comun. Mus. Ciênc. Tecnol. PUCRS. 7:41–150). In the present study, we found the clutches in open savanna, at ca. 1000 m from the nearest *Araucaria* forest. Forested areas within the area we sampled have been reduced by *Pinus* plantations, but small areas of *Araucaria* forest still exist. Morphology of the species, characteristic of the family Leiosauridae (long fingers and very long tail), revealed that it has an unquestionable arboreal habit, but the data presented in this study suggest that further investigation of the non-arboreal aspects of *A. grilli* behavior, of which one appears to be oviposition, is warranted.

Submitted by **MARTIN SCHOSSLER, LAURA VERRASTRO,** and **DENISE MELLO MACHADO,** Laboratório de Herpetologia, Departamento de Zoologia, Instituto de Biociências, Universidade Federal do Rio Grande do Sul, Av. ASPIDOSCELIS TIGRIS TIGRIS (Great Basin Whiptail). **DIET**. *Aspidoscelis tigris*, one of the largest whiptail species in North America (Stebbins 2003. Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin, Boston, Massachusetts. 558 pp.), is a wide-ranging forager known to prey on diverse invertebrates (Pianka 1970. Ecology 51:703–720). Although records exist of *A. tigris* preying on small lizards, *Sceloporus graciosus* is not among the reported prey. We report the first observation of predation on *S. graciosus* by *A. tigris*.

At 1155 h on 8 July 2006 (sunny, hot [air temperature just over 41°C]), while looking for lizards just east of Ubehebe Crater (37°01'04"N, 117°26'38"W, datum: NAD83; elev. 2260 m), Death Valley National Park, we observed an adult *A. tigris* (ca. 320 mm total length) foraging on an open slope with a sand/gravel substrate. We followed the *A. tigris* until it took refuge in the shade of a shrub, approached it to ca. 1 m and then remained motionless; based on its behavior, the lizard did not seem disturbed by our presence. At 1159 h, the *A. tigris* began searching for prey and dug into the sand around the base of the shrub. Almost instantly, a ca. 70 mm total length *S. graciosus* appeared, fled toward us, and the *A. tigris* almost as rapidly caught it at mid-body, but closer to the hind limbs. For a few seconds, the *S. graciosus* vigorously tried to escape but the *A. tigris* kept a firm hold, and shook and chewed it repeatedly. Once the *S. graciosus* ceased struggling, the *A. tigris* began to swallow it hind end first. During the process, the tail of the *S. graciosus* broke, dropping on the sand. After swallowing the *S. graciosus*, the *A. tigris* began to investigate the nearby substrate with its tongue. When the *A. tigris* found the dropped tail, this was also swallowed. After ingestion at 1201 h, the *A. tigris* remained under the shrub but in a sunny patch. The entire predation event took just under 2 min; during this time, the *A. tigris* remained < 50 cm from the base of the shrub.

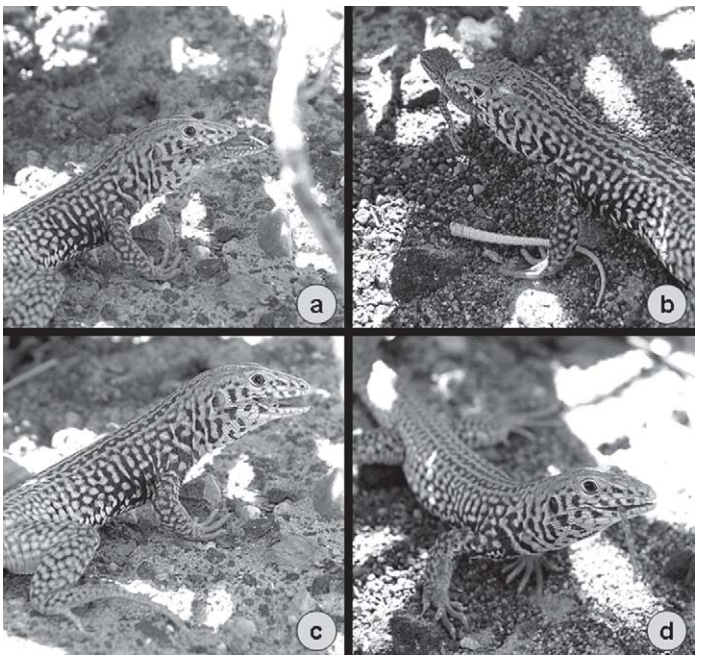

FIG. 1. A large *Aspidoscelis tigris* preying on a *Sceloporus graciosus*: a) Swallowing process, hind parts first; b) Note the tail of the *S. graciosus* just under the whiptail's head; c) Termination of swallowing the *S. graciosus*; and d) *A. tigris* swallowing the tail of the *S. graciosus* found on the sand.

We took 20 photos to document the process; some of them are presented in Fig. 1. We thank J.-F. Desroches and M. P. Hayes for useful comments.

Submitted by **DANIEL POULIOT** and **NATHALIE CÔTÉ**, 4230 Louis-Lacroix #1, Trois-Rivières, Québec, Canada, G8Y 5V2 (e-mail [DP]: crotaluspou@hotmail.com).

CARLIA GRACILIS (Slender Rainbow Skink) and ***GLAPHYROMORPHUS DARWINIENSIS*** (Darwin Skink). **FEEDING AGGREGATION.** Lizards of the Indo-Australian skink genera *Carlia* and *Glaphyromorphus* are small terrestrial insectivores (Greer 1989. The Biology and Evolution of Australian Lizards. Surrey Beatty & Sons, Chipping North, New South Wales, Australia. 264 pp.). Feeding aggregations in these genera are unreported. Here, I provide an observation of a multi-species feeding aggregration of members of these two genera from northern Australia.

At 0830 h on 30 October 2004, over 30 lizards were observed feeding on alate termites in an open patch of leaf litter in a suburban garden in Darwin, Northern Territory, Australia (UTM: 701480E, 8629686N, datum: WGS84; elev. 10 m). The site was observed from a distance of 4 m using a pair of 10 × 42 binoculars. Six lizard species were recorded feeding in an area 4 m ×

3 m: *Carlia gracilis* (ca. 20 sightings, precise number of individuals unknown), *Glaphyromorphus darwiniensis* (ca. 10 sightings), *Glaphyromorphus douglasi* (1 individual), *Lophognathus temporalis* (a female or juvenile male), and *Hemidactylus frenatus* (2 individuals). The *Glaphyromorphus darwiniensis* and *C. gracilis* were observed feeding together separated by less then a body length; occasionally upon contacting or nearly contacting another individual, a skink would flee a short distance (< 20 cm). Otherwise, I observed no aggressive behaviour even though I had observed intraspecific chasing and fighting in these two species at the same location earlier in the year. Winged termites were abundant in the air and lizards took these when they landed on leaves, the adjacent shed wall and the leaves of palm saplings < 10 cm above the ground. Observations were made until 0850 h, at which time termite numbers in the air had declined to nearly zero and the number of lizards visible was likewise reduced. A pitfall trapline 5 m long with 3 pitfall traps ca. 13 m from the location of the feeding aggregation yielded no captures that day; for 36 operational days between 29 September and 20 December 2004, I captured an average of 0.81 lizards per day, indicating that the aforementioned feeding aggregation represented a local high-density circumstance.

CERCOSAURA ARGULUS (White-lipped Cercosaura). **ENDOPARASITES.** *Cercosaura argulus* occurs in French Guiana, Colombia, Ecuador, Peru, Bolivia, and Brazil (Avila-Pires 1995. Lizards of Brazilian Amazonia [Reptilia: Squamata], Zoologische Verhandelingen National Natuurhistorisch Museum, Leiden, Netherlands. 706 pp.). In Peru, it has been recorded in the Departments of Amazonas, Huánuco, Loreto, Madre de Diós and Pasco (Lehr 2002. Amphibian und Reptilien in Peru, Die Herpetofauna entlang des 10. Breitengrades von Peru: Arterfassung, Taxonomie, ökologische Bemerkungen und biogeographische Beziehungen, Natur und Tier – Verlag GmbH. Münster, Germany. 208 pp.). To our knowledge, no reports exist of helminths in *C. argulus.* The purpose of this note is to establish an initial helminth list for *C. argulus* by reporting it as a host for nematodes in Peru.

Five *C. argulus* (4 females, 1 male: mean SVL = 38 mm ± 4.3 SD, range: 33–43 mm) collected in 1963 or 1972 from Loreto Department, Peru, were borrowed from the Texas Cooperative Wildlife Collections (TCWC), Texas A&M University, College Station, Texas. Four (TCWC 36724, 36725, 38144, 41833) were from the vicinity of Moropon, on Río Nanay (3°43'S, 73°14'W, datum: WGS84; elev. 100 m), one (TCWC 39038) was from Mishana, on Río Nanay (3°52'S, 73°29'W; elev. 100 m). The esophagus, stomach, small and large intestines were opened and separately examined for helminths under a dissecting microscope. The body cavity was also examined for helminths. Four species of nematodes, *Oswaldocruzia peruensis* (two adult males in the small intestine of TCWC 41833), *Physaloptera* sp. (three larvae in the stomach of TCWC 36724, one larva in the large intestine of TCWC 36725, one larva in the small intestine of TCWC 38144), unidentified cosmocercid (one mature female each in the small intestine of TCWC 36725 and 41833), unidentified acuariid (one larva in the small intestine of TCWC 39038). Nematodes were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as: *Oswaldocruzia peruensis* (99356); *Physaloptera* sp. (99359); acuariid (99357); cosmocercid (99358).

Oswaldocruzia peruensis was described from *Sternocercus roseiventris* from Peru (Ben Slimane et al. 1995. Bull. Mus. Nat. Hist. Nat. 17:77–82). Bursey et al. (2005. Comp. Parasitol. 72:50–68) also found it in *Anolis punctatus* from Peru. Larvae of *Physaloptera* sp. and the Acuariidae are common in amphibians and reptiles (Goldberg et al. 1993. Bull. S. California Acad. Sci. 92:43–51). Insects act as intermediate hosts (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission. CABI Publishing, Wallingford, Oxon, U.K. 650 pp.); thus physalopteran and acuariid larvae might be expected in any insectivore. Examination of a male is needed to identify cosmocercid nematodes to species. Infection is direct with no intermediate host utilized (Anderson, *op. cit.*). *Oswaldocruzia peruensis*, *Physaloptera* sp., acuariid and cosmocercid nematodes in *C. argulus* are new host records.

We thank Toby Hibbitts (Department of Wildlife and Fisheries, Texas A&M University) for permission to examine specimens and Sarah Goldsberry and Cassie Ho (Whittier College) for assistance with dissections.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu).

CNEMIDOPHORUS NATIVO (NCN). **PREDATION**. *Cnemidophorus nativo* is a parthenogenetic whiptail lizard endemic to restingas (coastal sand dune habitats covered with herbaceous and shrubby vegetation) in the states of Bahia and Espírito Santo, Brazil (Rocha et al. 1997. Herpetologica 53:374–352). Some information has been published on its ecology (e.g., Bergallo and Rocha 1994. Australian J. Ecol. 19:72–75; Menezes et al. 2004. J. Herpetol. 40:280–282), but data on its predators are lacking. During a herpetological survey of Parque Estadual Paulo Cesar Vinha (PEPCV), a largely undisturbed restinga in the municipality of Guarapari, Espírito Santo, Brazil (20°35'S, 40°24'W; near sea level), we obtained data on two native predators of *C. nativo*. Here, we report on two observations of predation by the colubrid snake *Philodryas patagoniensis* and one observation of predation by the tropidurid lizard *Tropidurus torquatus*.

We observed predation attempts by *P. patagoniensis* on each of 27 December 2005 and 13 January 2006. Both observations were made between 1100 and 1200 h, which correspond, in part, to the interval of highest activity by *C. nativo* in this area (PLP, unpubl. data). The first observation was made on a sunny day in a forest trail developed for human access to the beach. The trail, ca. 2–3 m wide, cuts through a ca. 1.5 km of forested area. When found, the snake was coiled around the lizard, which was immobilized in a head down position, and the snake was grasping its tail (Fig. 1). During photography of the event, we disturbed the snake, which took flight immediately, leaving the lizard on the ground. The

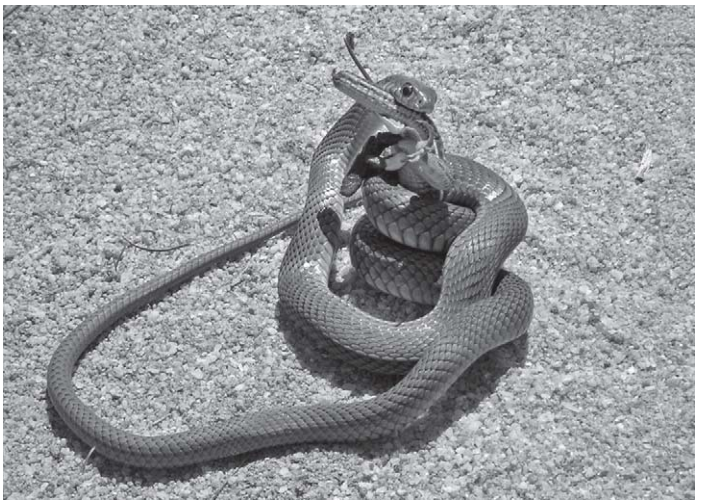

FIG. 1. *Philodryas patagoniensis* preying on an adult *Cnemidophorus nativo*. Photo by Ana C. Pavan.

whiptail remained motionless for a few seconds then also fled. The second observation was made in a shrubby vegetation-dominated portion of the PEPCV. In this case, we only had the time to see the *C. nativo* (certainly an adult based on its size) hanging from the mouth of the snake before it retreated into an area with taller vegetation still holding the lizard.

Philodryas patagoniensis is mainly a terrestrial species known to prey on a variety of vertebrates (Marques et al. 2001. Serpentes da Mata Atlântica: Guia Ilustrado para Serra do Mar. Holos, Ribeirão Preto, São Paulo, Brazil. 184 pp.). Gonzaga et al. (1997. Herpetol. Rev. 28:154) and Rocha and Vrcibradic (1998. Ciência e Cultura 50:364–368) published a few data on the food habits of this species in a restinga habitat, mentioning scincid lizards (*Mabuya* spp.), a Four-eyed Opossum (*Metachirus nudicaudatus*), and nestlings of an emberezid bird (*Coereba flaveola*) as prey. This represents the first report of *P. patagoniensis* predation on *C. nativo*.

At 1100 h on 25 January 2006, we observed a large (ca. 10 cm SVL) adult *Tropidurus torquatus* preying on an adult *C. nativo*. When first found, the *C. nativo* was in the tropidurid's mouth, but was clearly still alive and seemed to be attempting to release itself from its predator. The *T. torquatus* fled with the whiptail in its mouth immediately after noticing our presence, and we did not see the outcome of the event. *Tropidurus torquatus* is an ambush-foraging lizard known to feed on diverse prey, but mainly arthropods (e.g., Bergallo and Rocha, *op. cit.*), but may also consume plant material (e.g., Teixeira 2001. Atlantica, Rio Grande 23:77–84; Rocha et al. 2002. Brazilian J. Biol. 62: 285–291), other lizards (e.g., Araújo 1991. Rev. Brasileira Biol. 51:857–865; Teixeira, *op. cit.*) and even small mammals (J. L. Gasparini and PLP, unpubl. data) in its diet. However, this is the first report of *C. nativo* as prey.

We thank J. L. Gasparini and D. Pavan for guidance and assistance during the work at PEPCV. A. C. Pavan made her photographs available, R. Montesinos helped in the fieldwork, and D. Vrcibradic provided helpful suggestions on the manuscript. Fellowships from the Conselho Nacional de Desenvolvimento Científico e Tecnológico (PIBIC/CNPq) supported both authors.

Submitted by **PEDRO L. PELOSO** (e-mail: pedropeloso@terra.com.br) and **SILVIA ELIZA PAVAN,** Departamento de Biologia, Universidade Federal do Espírito Santo, Av. Marechal Campos 1468, Maruípe, 29040-090 Vitória, Espírito Santo, Brazil.

CNEMIDOPHORUS OCELLIFER (Brazilian Whiptail Lizard). **FORAGING BEHAVIOR**. Climbing behavior has been described for a number of lizards, but these represent primarily arboreal or semi-arboreal species (Pianka 1973. Ann. Rev. Ecol. Syst. 4:53–74; Vitt and Zani 1998. J. Trop. Ecol. 14:63–86). However, except for the genus *Kentropyx* (Martins 1991. Stud. Neotrop. Fauna Environ. 26:179–190), climbing behavior is undescribed among Brazilian teiid lizards. All other species are typically ground-dwelling (Vitt 1995. Occ. Pap. Oklahoma Mus. Nat. Hist. 1:1–29; Mesquita and Colli 2003. J. Herpetol. 37:498–509). Here, we describe arboreal behavior in the Brazilian teiid, *Cnemidophorus ocellifer*.

Our observations were made in the Reserva Particular do Patrimônio Natural Fazenda Almas, located between São José dos Cordeiros and Sumé, State of Paraíba, Brazil (07°28'S, 36°52'W; elev. 760 m). Between 1100 h and 1200 h on 9 November 2005, we observed 6 *C. ocellifer* foraging in roadside vegetation, which included herbaceous vegetation within a stand of a dozen small woody shrubs up to 0.7 m high. Three of these individuals displayed non-terrestrial foraging behavior. The behavior began with an investigation of the soil, where leaf litter was overturned in search of prey. Each lizard would then climb into a shrub to a height of ca. 40 cm, capturing small insects (orthopterans and membracids with body lengths < 5 mm) along its stem and branches until it reached the top of the shrub. After reaching the top of the shrub, the animal would first look down, scan the ground, and then jump down in an attempt to capture insects that had been dislodged during its ascent. One of the *C. ocellifer* exhibited this behavioral sequence only once, but the other two animals each repeated it four or five times, in each case always climbing the same shrub. Repeated use of a single plant may have been partly related to the fact that only four of the shrubs provided a substrate appropriate for climbing, although it is also possible that the presence of invertebrate prey was also a factor. Both these individuals also repelled other *C. ocellifer* repeatedly and aggressively whenever they approached the plants on which the former were foraging, as though they were defending a resource.

The climbing behavior we observed has not been reported previously for teiids native to the Caatinga, a xeric shrubland biome of northeastern Brazil (see Ab'Saber 1974. Geomorfologia 43:1–39). Such exploitation of a novel habitat may represent a behavioral strategy aimed at reducing potential competition with the much larger, syntopic teiid *Ameiva ameiva* (mean body weight ca. 60 g vs. 12 g in *C. ocellifer* [Vitt 1995. Occ. Pap. Oklahoma Mus. Nat. Hist. 1:1–29]), which we also observed in the vicinity of the shrubs. However, more systematic observations of the behavior will be necessary to understand its ecological implications.

Submitted by **FAGNER RIBERO DELFIM**, Departamento de Sistemática e Ecologia, Universidade Federal da Paraíba, 58.051-900, João Pessoa, Paraíba, Brazil; **WASHINGTON LUIZ DA SILVA VIEIRA**, Departamento de Sistemática e Ecologia,

Universidade Federal da Paraíba, 58.051-900, João Pessoa, Paraíba, Brazil; and **STEPHEN FRANCIS FERRARI**, Departamento de Biologia, Universidade Federal de Sergipe, 49.100-000, São Cristóvão, Sergipe, Brazil.

CNEMIDOPHORUS OCCELIFER (Whiptail Lizard)**. PREDATION.** *Cnemidophorus ocellifer* is a conspicuous element of open habitats in Brazilian Cerrado (Mesquita and Colli 2003. J. Herpetol. 37:498–509). Despite this, field observations of predation on this species are scarce. Hence, we report an observation of predation on *C. ocellifer* in the Brazilian Pantanal.

On 10 September 2001 at ca. 0900 h, we captured a juvenile (245 g) Road Hawk, *Ruphornis magnirostris*, using a 12 m × 2.6 m mist-net in a semi-deciduous forest association popularly known as "cordilheira" at Retiro Novo Ranch, Estado do Mato Grosso (16°14'13"–16°23'47"S, 56°17'45"–56°22'31"W; datum: South America 69; elev. 240 m). This association, located on fluvial sediments on the margins of abandoned riverbeds, occurs in narrow bands ranging from but a few meters up to 100 m wide. After administering an emetic solution of potassium antimony tartarate ($C_4H_4KO_7Sb$) at a concentration of 1 mg/kg of body mass, the hawk regurgitated an entire juvenile *C. occelifer* (54.0 mm SVL). The bird was then measured and released.

Accipitrid hawks are known lizard predators (Rivas et al. 1998. Herpetol. Rev. 29:238–239; Rivero and Manzanilla 2006. Herpetol. Rev. 37:85), but to our knowledge, this is the first predation record on an actively foraging teiid lizard.

Mist netting was done under license number 021/06-GEREX-I.IBAMA/MT awarded to Jõao Batista de Pinho from CEMAVE/IBAMA. The lizard (UFMT 4389) was deposited in the herpetological collection in the Vertebrate Collection of Universidade Federal do Mato Grosso.

CROTAPHYTUS BICINCTORES (Great Basin Collared Lizard). **DIET.** Lizards of the genus *Crotaphytus* feed predominantly on arthropods, such as orthopteran, coleopteran, hymenopteran, and lepidopteran insects (Fitch 1956. Univ. Kansas Mus. Nat. Hist. Publ. 8:213–274). Nevertheless, *Crotaphytus* lizards have been reported to feed on small vertebrates, mainly other lizards but occasionally snakes (Husak and Ackland 2000. Herpetol. Rev. 31:47), birds (Best and Pfaffenberger 1987. Southwest. Nat. 32:415–426), and rodents (McAllister and Trauth 1982. Southwest. Nat. 27:358–359; Montanucci 1971. Herpetologica 27:183–197). Lizards that *Crotaphytus* have been reported to consume include *Uta stansburiana* (Springer 1928. Copeia 169:100–104); *Aspidoscelis* sp., *Phrynosoma modestum* (Best and Pfaffenberger 1987. Southwest. Nat. 32:415–426); *Xantusia vigilis* (Banta 1960. Wasmann J. of Biol. 18:309–311); *Sceloporus undulatus*, *Scincella lateralis* (McAllister 1985. Southwest. Nat. 30:597–619); and *Eumeces sp.* (Fitch 1956. Univ. Kansas Mus. Nat. Hist. Publ. 8:213–274; Lappin 2002. Herpetol. Rev. 33:305–306). Here, we provide the first report of *Crotaphytus bicinctores* eating *Sauromalus ater* (Common Chuckwalla).

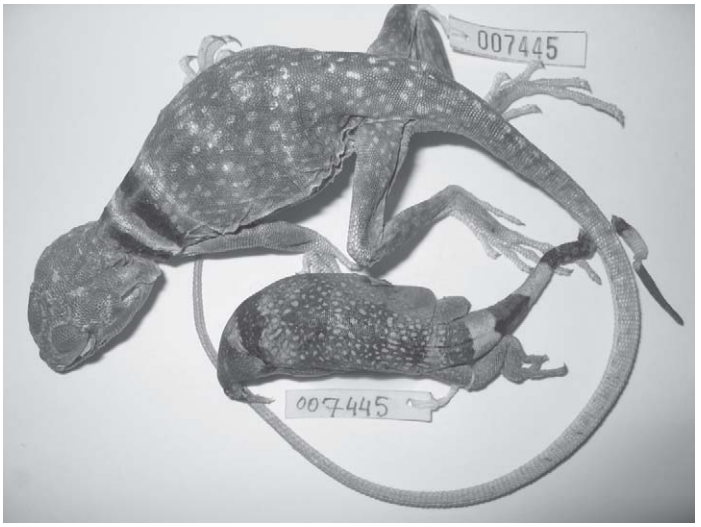

FIG. 1. A *Crotaphytus bicinctores* (weighing 17.6 g) with its prey, a young-of-year *Sauromalus ater* (weighing 6.6 g).

On 1 April 1996, ALH collected an adult female *C. bicinctores* (89 mm SVL, 17.6 g) in the Newberry Mountains, Clark Co., Nevada, USA. Upon capture, ALH noticed that a tail was hanging from its mouth. The lizard was later dissected and the stomach contained an almost intact young-of-the-year *S. ater* (48 mm SVL, 6.6 g; Fig. 1). The relative prey mass of the *S. ater* was 37.5%. The female *C. bicinctores*, which had likely recently emerged from hibernation, appeared very emaciated (note its tail in Fig.1).

A study on the closely related *Crotaphytus collaris* revealed that the total mass of prey items contained in the stomachs of 48 lizards averaged 1.11 g (Husak and McCoy 2000. Texas J. Sci. 52:93–100). The size of the prey item we report here is much larger, and feeding on such large prey is probably infrequent for *C. bicinctores*. As noted above, the female *C. bicinctores* seemed in poor condition. To assess whether this was the case, we weighed 8 non-gravid female *C. bicinctores* of similar size (mean = 88.6 mm SVL, SD = 2.2 mm; range: 85–91 mm) collected around the same locality. The mean mass of the 8 females was heavier (mean = 23.2 g, SD = 5.5 g; range: 13.4–32.3 g) than this female, suggesting that she was on the poor condition end of variation in mass. We believe that the condition of the female *C. bicinctores* at emergence from hibernation may be one factor that led her to feed on such large unusual prey.

The *C. bicinctores* and its *S. ater* prey were deposited in the Marjorie Barrick Museum of Natural History, the University of Nevada, Las Vegas (MBM 7445). Specimens were collected under permit S27454 to ALH from the Nevada Department of Wildlife. Specimens of *Crotaphytus bicinctores* examined: MBM 443, 550, 1031, 1035, 2284, 3856, 3871, 7228.

CTENOSAURA SIMILIS (Black Spiny-tailed Iguana). **PREDATION.** *Ctenosaura similis* is exotic to Florida (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publishing Co., Malabar, Florida. 155 pp.). In particular, they were released on Gasparilla Island (Charlotte and Lee Counties) 30–35 years ago, where they are now abundant (Krysko et al. 2003. Florida Sci. 66:141–146). This species may pose a threat to a number of endemic threatened and endangered species on Gasparilla Island such as eggs of nesting shore birds, beach mice, hatchling sea turtles and gopher tortoises (*Gopherus polyphemus*) (Krysko et al., *op. cit*.), but to date, local predators on *C. similis* are unreported (Meshaka et al., *op. cit.*). Indigenous predators might exert one controlling influence on exotic Florida herpetofauna (Butterfield et al. 1997. *In* Simberloff et al. [eds.], Strangers in Paradise, pp. 123–138. Island Press, Washington, DC). Hence, we report evidence of Bobcat (*Felis rufus*) predation on *C. similis* on Gasparilla Island.

On 17 April 2007, RME located 3 *F. rufus* scats on the sandy aprons of *C. similis* burrows in coastal strand habitat (FDEP 2002. Gasparilla Island Unit Management Plan. Florida Dept. Environ. Protection, Tallahassee. 68 pp.) within Gasparilla Island State Park (larger *C. similis* often use Gopher Tortoise burrows, but cohabitation has not been observed [McKercher 2001. *Ctenosaura pectinata* (Iguanidae) on Gasparilla Island, Florida: Colonization, habitat use and interactions with *Gopherus polyphemus*. MS Thesis, Univ. Florida, Gainesville. 117 pp.]). Examination of the *F. rufus* scats revealed fragments of *C. similis*. Notable among the fragments was a desiccated right front forefoot ca. 3.5 cm long, suggesting a mature lizard of reproductive size had been taken. Given the large *C. similis* population on Gasparilla Island as indicated by the high density of active burrows (ca. 42/ha) and large number of juveniles we located with minimal searching of the area in which we found the scats, bobcat predation alone is unlikely to suppress *C. similis* populations. Population reduction of this invasive species on Gasparilla Island will likely require a comprehensive integrated pest management plan that incorporates multiple control tools and strategies and involves the responsible government entities on Gasparilla Island (Charlotte County and Lee County governments and Florida Florida Fish and Wildlife Conservation Commission). In fact, the management plan for Gasparilla Island State Park recognizes the need for ctenosaur management to protect gopher tortoises, but also recognizes such management would only be effective if government entities coordinate efforts (FDEP, *op. cit.*).

CHRISTIE**, Charlotte County Environmental & Extension Services, 25550 Harbor View Rd., Suite 2, Port Charlotte, Florida 33980-2503, USA; **BERNICE CONSTANTIN**, USDA/Wildlife Services, 2820 East University Ave., Gainesville, Florida 32641, USA.; and **ROBERT CHRISTIE**, Florida Department of Environmental Protection, Florida Park Service, Gasparilla Island State Park, Boca Grande, Florida 33921, USA.

CYCLURA CYCHLURA CYCHLURA (Andros Iguana). **SCOLIOSIS; KYPHOSIS.** Spinal curvatures are reported infrequently in wild lizard populations (Frutos et al. 2006. Herpetol. Rev. 37:468–469; Mitchell and Georgel 2005. Herpetol. Rev. 36:183). These infrequent accounts have reported no obvious limitations to mobility or prey capture. However, spinal malformation

FIG. 1. Scoliosis of the lower back (A) and kyphosis of the tail (B) in an adult female *Cyclura c. cychlura* from South Andros, Bahamas.

impact on fitness (e.g., affecting production of viable offspring) is unknown among wild lizard populations. To our knowledge, no documented reports exist of lizards with malformed spinal columns reproducing successfully. Here, we report on an iguanid lizard with a case of scoliosis and kyphosis that produced viable eggs and offspring in the wild.

On 9 June 2004, we captured an adult female *Cyclura cychlura cychlura* (34.4 cm SVL, 1.81 kg) while she was guarding her eggs oviposited within an active termite (*Nasutitermes rippertii*) mound on an unnamed cay in Lisbon Creek, South Andros Island, Bahamas (24°05'24"N, 77°42'42"W, datum: WGS84; elev. 1.5 m). Nesting within *N. rippertii* mounds and aggressive nest-guarding behavior is typical for females of this subspecies (Knapp et al. 2006. Can. J. Zool. 84:1566–1575). The iguana exhibited a convex curvature of the spine (scoliosis) anterior to the pelvic girdle, and a concave spinal curvature over the pelvic girdle. Multiple lateral curvatures (kyphosis) spanned the entirety of the tail (Fig. 1). Despite these malformations, the lizard seemed healthy, had normal use of all limbs, and aggressively defended her nest from us as we approached. As part of our study, we excavated the nest and discovered seven eggs. The clutch size fell within one standard deviation of clutch size for our 2004 sample (N = 34 clutches; mean = 9.8, SD = 3.3). Mean egg length (67.3 mm) also was within one standard deviation of the 2004 sample (N = 34 clutches; mean = 70.7, SD = 3.6). However, mean egg width (37.2 mm) and mass (53 g) were slightly lower than one standard deviation of the 2004 sample (N = 34 clutches; mean = 40.3, SD = 2.8; mean = 59.8, SD = 4.9, respectively). We replaced the eggs and returned 76 days later to excavate the nest to determine hatching success. All eggs hatched within the nest and none of the hatchlings were malformed. Though unconfirmed, the spinal curvatures may have resulted in a restricted cloacal opening and constrained egg width, while a reduced abdominal cavity may have caused the below average egg mass.

We thank the Bahamas Department of Agriculture for permission to conduct our research and for issuing permits. This research was supported by the John G. Shedd Aquarium and with a grant from the Association of Zoos and Aquariums (AZA) Conservation Endowment Fund.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). **NESTING**. Over the past century, *Hemidactylus turcicus* has dramatically expanded its introduced range in North America (Fowler 1915. Proc. Acad. Nat. Sci. Phila. 67:244–269; Robinson and Romack 1973. J. Herpetol. 7:311–312). Small body size, calcareous eggs, a nocturnal lifestyle, a preference for human habitats (Meshaka 1995. Florida Sci. 58:10–15; Nelson and Carey 1993. Northeast Gulf Sci. 13:53–58), and an affinity of humans for the species (Locey and Stone 2006. J. Herpetol. 40:528–532) seem to have contributed importantly to the frequency and success of its human-aided saltatory dispersal. Less attention has been paid to factors that may promote successful diffusion dispersal and local expansion of established populations. Here, we report *H. turcicus* nesting behaviors that may facilitate diffusion dispersal of hatchlings to unoccupied habitats.

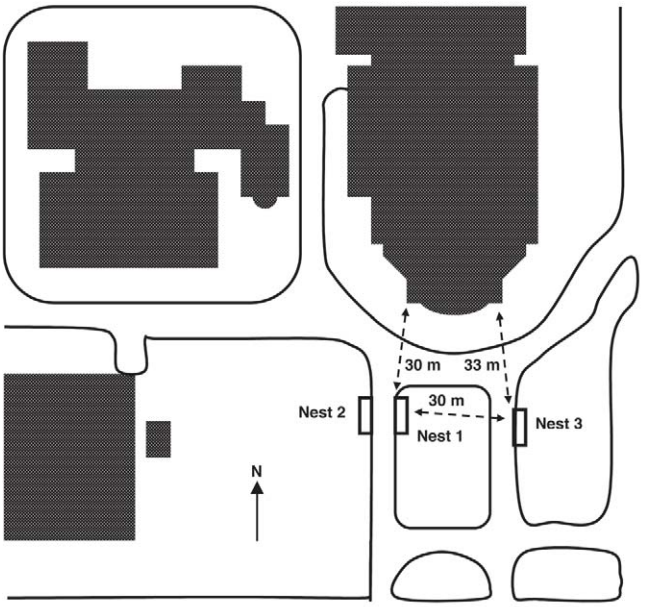

FIG. 1. Map of *Hemidactylus turcicus* nest locations relative to the population boundary. Campus buildings (stippled) shown represent the southeast corner of the population boundary (Locey and Stone 2006. J. Herpetol. 40:528–532).

On 25 August 2006, we found a communal nest (Nest 1, Fig. 1) of 10 unhatched *H. turcicus* eggs inside a storm sewer 35 m beyond a population boundary that was documented via intense censusing (Locey and Stone 2006. J. Herpetol. 40:528–532) of the campus of the University of Central Oklahoma, Edmond, Oklahoma (35.65503°N, 97.47302°W, datum: WGS84; elev. 360 m). These eggs were located on a soil substrate level to the street. The eggs were in a corner of the storm sewer, covered by ca. 20 cm of leaf litter, sticks, and debris. We revisited Nest 1 the next night and found 12 eggs, three of them hatched. On that same night we found another nest (Nest 2, Fig. 1) of five unhatched eggs in a different storm sewer on the opposite side of the street. Nest 2 was covered by ca. 20 cm of leaf litter and debris, and was elevated ca. 15 cm above the sewer bottom on a mound of soil. We revisited the nests on 9 September 2006: Nest 1 contained six unhatched and three hatched eggs; Nest 2 contained two unhatched and two hatched eggs. That same night, we found yet another nest (Nest 3, Fig. 1) located inside a different storm sewer on an adjacent street. Nest 3 contained one hatched egg and remnants of egg shells. The nest site was located in the only dry area in the storm sewer. On 15 October 2006, we visited the nests: Nest 1 had five unhatched eggs and one hatched egg; Nest 2 had one unhatched egg; and Nest 3 had no eggs. All three nests were similar in structure and were located on the most elevated portion of the storm sewer. We searched all storm sewers and areas near campus buildings, streets, and parking lots. We found several adult and hatchling geckos in storm sewers at each corner of the population, but no other nests.

We found no geckos east of Nest 3 and only two adults south of Nests 1 and 2, both occupying the same storm sewer ca. 30 m south of Nest 1.

Communal nests have been reported for *H. turcicus* elsewhere (Punzo 2001. Florida Sci. 64:56–66; Selcer 1986. Copeia 1986:956–962). However, this is the first record of *H. turcicus* nests located on the periphery of an introduced population, outside the immediate vicinity of buildings. These sewers are unheated and therefore probably unoccupied by geckos during winter months. If true, females would need to disperse from buildings to lay eggs in storm sewers in the same season. These observations suggest that hatchlings may be placed in habitats where competition for resources is minimized, and diffusion dispersal promoted.

Submitted by **KENNETH J. LOCEY** (e-mail: klocey@ucok.edu) and **PAUL A. STONE** (e-mail: pstone@ucok.edu), Department of Biology, University of Central Oklahoma, Edmond, Oklahoma 73034, USA.

HOLBROOKIA APPROXIMANS (Speckled Earless Lizard). **PREDATION.** The phrynosomatid lizard, *Holbrookia approximans*, has a broad distribution throughout the southwestern United States and much of northwest-central México (Conant and Collins 1998. A Field Guide to the Reptiles and Amphibian of Eastern and Central North American, 3rd ed. Houghton Mifflin, Boston, Massachusetts. 429 pp.; Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin, New York, New York. 533 pp.). These guides mention nothing about its predators, but Smith (1979. Handbook of Lizards. Comstock Publ. Assoc., Cornell University Press, Ithaca, New York. 557 pp.) noted that a large (size unspecified) *Bufo* (= *Cranopsis*) *alvarius* ate an earless lizard, and also mentioned hawks (species not specified) as predators. Here, we add the Burrowing Owl, *Athene cunicularia,* to the set of predators of *H. approximans*.

Our data were obtained during a survey of the winter ecology of *A. cunicularia* at Llano de la Soledad (25°05'44.92"N, 100°48'37.46W, datum: WGS84; elev. 1850 m), La Trinidad (24°56'29.80"N, 100°28'41.91W; elev. 1850 m), and La Hediondilla (25°05'44.92"N, 100°48'37.46W; elev. 1890 m) in the municipality of Galeana, Nuevo León, México. Survey areas were open grassland; on their periphery, an association dominated by *Larrea tridentata, Flourensia cernua, Rhus microphylla, Prosopis* sp., and *Acacia* sp. was present. Agriculture, largely consisting of potatoes (*Solanum tuberosum*) is also extensive in the area. On 12 December 2002, during analysis of 125 regurgitated pellets and prey remains representing an unspecified number of occupied *A. cunicularia* nests and roosting mounds at these localities, we found one pellet containing the upper portion of the body (395 mm; size of body fragment only) of an adult *H. approximans*.

With a broad distribution across the Americas, *A. cunicularia* has the opportunity to take diverse prey (American Ornithologists Union 1983. Check-list of North American Birds, 6th ed. Allen Press, Lawrence, Kansas. 829 pp.; Wellicome and Holroyd 2001. J. Raptor Res. 35:269–273). Mammals, birds, and invertebrates dominate the prey of *A. cunicularia*, which has been the focus of a number of dietary studies over the past 40 years (Grant 1965. Loon 37:2–17; Coulombe 1971. Condor 73:162–176; Marti 1974. Condor 76:45–61; Valdez-Gómez 2003. Dieta del tecolote llanero occidental, *Athene cunicularia hypugae* [Bonaparte, 1825], durante su estancia invernal en el Bajío Mexicano. Tesis Profesional, Universidad de Guadalajara, Centro Universitario de Ciencias Biológicas y Agropecuarias, División de Ciencias Biológicas y Ambientales, Guadalajara, México. 41 pp.), a diet in which relatively few amphibians and reptiles appear (Moulton et al. 2005. J. Raptor Res. 39:429–438). Our observation is the first record of *H. approximans* as prey of *A. cunicularia*.

HOPLODACTYLUS CHRYSOSIRETICUS (Goldstripe Gecko). **BODY TEMPERATURE**. *Hoplodactylus chrysosireticus* is a small (maximum 75 mm SVL) endangered New Zealand gecko found only on Mana Island (Cook Strait) and on the mainland at Taranaki (Gill and Whitaker 2001. New Zealand Frogs and Reptiles. David Bateman, Auckland. 112 pp.). It is viviparous, nocturnal, and arboreal and, like many other nocturnal *Hoplodactylus*, can be found basking during the day (e.g., Common Gecko, *H. maculatus* [Werner and Whitaker 1978. New Zealand J. Zool. 5:375–393]). Here, I report on the first account of body temperatures for *H. chrysosireticus* during both diurnal emergence and nocturnal foraging.

During a larger study addressing lizard physiology on Mana Island (41°40'S, 174°00'E; elev. 121 m), I obtained body temperature data on *H. chrysosireticus*. On 4 days between 14 and 25 November 2003 (austral spring), I captured by hand *H. chrysosireticus* that had emerged on vegetation (flax, *Phormium tenax* and *P. cookianum*, N = 25; and mahoe, *Melicytus ramiflorus*, N = 2). All searches and captures were made between 1400–1700 h and 2100–2400 h along the lower 100 m of the Weta Valley trail.

Body temperature (T_b) was measured cloacally to the nearest 0.1°C using a quick reading mercury thermometer (Avinet Inc, Dryden, New York, USA). All T_bs were recorded within 5 sec of initial capture to avoid handling effects. Environmental temperatures were also measured, including air temperature (T_a) in the shade at the height of the gecko at the time of capture and air temperature within the base of flax bushes (T_f; most individuals were located on flax). Sex was determined by presence of enlarged hemipenal sacs and femoral pores in males, and females were recorded as pregnant or non-pregnant based on abdominal palpation (see [Wilson and Cree 2003. Austral Ecol. 28:339–348] for accuracy of this procedure in other viviparous New Zealand geckos). All individuals had SVL (± 1 mm) and mass (± 0.1 g Pesola™) recorded and were semi-permanently marked with an individual number on the dorsal surface using a non-toxic pen (Sharpie, Bic Pens). Following processing, geckos were all released at the point of capture.

Twenty-seven adult *H. chrysosireticus* had their T_b measured

including 17 females (14 pregnant and 3 non-pregnant) and 10 males, with 21 captured during the day (6 males and 15 females) and 6 at night (4 males and 2 females). No pregnant females were captured at night.

Body temperatures were significantly higher during the day (t-test: t = -5.178, $P < 0.001$), and ranged from 10.5°C to 14.0°C at night (mean = 12.5 ± 0.7°C), and 17.0–27.9°C during the day (mean = 20.8 ± 0.8°C). Sample sizes were too small to determine statistical differences between T_b of males and females at night, and between pregnant and non-pregnant females during the day. Day T_b for pregnant females (mean = 20.3 ± 0.8°C; range = 17.0–27.9°C) and males (mean = 22.2 ± 1.6°C; range = 18.2–27.1°C) were not significantly different (t-test: t = 0.765, $P = 0.451$). Body temperature during the day also did not vary with SVL, mass, or an interaction of these terms ($P > 0.05$).

In all but two individuals, T_b was greater than T_a (day = 6.2 ± 0.8°C; night = 1.2 ± 0.4°C). The two individuals with T_b less than T_a were captured during the day in the shade (T_b 0.2°C and 0.3°C cooler than T_a). During the day, T_b was typically 7.4 ± 1.0°C greater than T_f. At night, T_b was similar to T_f, on average 0.1 ± 0.2°C less than T_f. In all but one case, T_a was greater than T_f during the day and less than T_f at night (mean difference = 1.2 ± 0.3°C).

The data presented here confirm diurnal emergence and basking in *H. chrysosireticus* to T_b above ambient environmental temperatures. The daily T_b of *H. chrysosireticus* is similar to other species of New Zealand geckos. For example, *H. maculatus* on Stephens Island (Takapourewa) forage at night with T_b ranging from 10–13°C and by diurnal basking during the day their T_b averages 20.6°C in males and 22.6°C in females; T_b of the sympatric diurnal gecko *Naultinus manukanus* averages 23.8°C during the day (Werner and Whitaker, *op. cit.*). Pregnant females of other *Hoplodactylus* species have higher T_bs compared with males and their non-pregnant conspecifics (Rock et al. 2000. Physiol. Biochem. Zool. 73:344–355). Thus, it was unexpected that pregnant *H. chrysosireticus* have a T_b similar to that of males. Diurnal basking behavior in nocturnal species is attributed to, among other factors, embryo development (Rock et al., *op. cit.*). An in-depth study of the thermoregulatory behavior of *H. chrysosireticus* may help to reveal what drives these species differences.

Thanks to S. Carver, H. Flannagan, N. Mana, and G. D. Timlin for their assistance in the field, and T. Whitaker for comments on the draft. This research was conducted with New Zealand Department of Conservation and Victoria University of Wellington Animal Ethics approval.

LEIOCEPHALUS CARINATUS ARMOURI (Northern Curlytail Lizard). **MOCKINGBIRD ATTACK; ASSERTION DISPLAYS.** *Leiocephalus carinatus armouri* is a well-established exotic species in Florida (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publishing Co., Malabar, Florida. 155 pp.; Smith and Engeman 2004. Florida Field Nat. 32:107–113; Meshaka et al. 2005. Southeast. Nat. 4:521–526). Various avian species are predators of *L. c. armouri* in Florida including the Northern Mockingbird (*Mimus polyglottos*) (Smith et al. 2006. Herpetol. Rev. 37:224). Here we report an attack by a *L. c. armouri* on a pre-fledgling Northern Mockingbird (*Mimus polyglottos)* in Florida.

At 1853 h on 31 July 2006, a sunny early evening (temperature ca. 27°C), HTS observed a pre-fledging stage *M. polyglottos* on the blacktop parking lot surface at the Woolbright Road colony of *L. c. armouri* located in Boynton Beach, Florida (see descriptions in Smith and Engeman 2003. Herpetol. Rev. 34:245°246; Smith and Engeman 2004, *op. cit.*). The fence line shrubbery at the site had been trimmed noisily earlier in the day and it is common to find pre-fledgling *M. polyglottos* and other birds displaced from nests in the shrubbery in the parking lot after these disturbances (HTS, pers. obs.). Judging from its size, plumage, clumsy behavior, inability to fly, and plaintive high-frequency begging calls, HTS estimated the bird to be 10–12 days old, and 20–25 g (see review in Derrickson and Breitwisch 1992. *In* Poole et al. [eds.], The Birds of North America, Species Account No. 7, Northern Mockingbird. American Ornithologists' Union, Washington, D.C. and the Academy of Natural Sciences, Philadelphia, Pennsylvania. 26 pp.).

This initial observation lasted about 2 min when the Mockingbird hobbled east about 2 m into the territory of a large (ca. 12–13 cm SVL) adult male *L. c. armouri* and was attacked at 1855 h with a "rush" (Smith and Engeman 2004, *op. cit.*). It appeared the lizard was attempting to grab the bird with open jaws. The bird escaped, running awkwardly about 2 m, at which point the lizard broke off its pursuit. Within a minute, the lizard assumed a vigilant posture on a cement parking curb stop, a favorite basking spot for this individual, and performed assertion displays (tail curled, and "wagging" [rotating/twitching] to the right and left) (Cooper 2001. Ethology 107:1137–1149; Smith and Engeman 2004, *op. cit.*). At 1859 h, the bird walked slowly west past the parking stop and was attacked a second time from a distance of about 1 m. This time the bird escaped by hopping into the air and then running about 2–3 m, at which time the lizard again broke off its attack. The lizard then held this position on the parking lot surface performing assertion displays until 1901 h, at which time it returned to the parking curb stop. At 1906 h, an exotic adult Ringed Turtle Dove (*Streptopelia risoria*) ca. 20–25 cm and 125–150 g (mass estimate from Hedrick et al. 2002. J. Exp. Biol. 205:1389–1409) pecking at seeds on the parking lot surface passed within 0.75 m of the *L. c. armouri* and the lizard retreated to its burrow, stopping briefly at the entrance while curling and wagging its tail before disappearing. This final behavioral display is typical for this species in Florida (Cooper 2001, *op. cit.*; HTS, unpubl. data; Smith and Engeman 2004, *op. cit.*). The *M. polyglottos* continued walking west and the dove continued northwest. The *L. c. armouri* was still out of sight in its burrow when observations were ended at 1915 h. Most likely, the larger Ringed Turtle Dove was responded to as a potential threat with a retreat, especially in light of the observation of the similar-sized adult Northern Mockingbird as a predator of *L. c. armouri* (Smith and Engeman 2006, *op. cit.*).

Submitted by **HENRY T. SMITH**, Florida Department of Environmental Protection, Florida Park Service, 13798 S.E. Federal Highway, Hobe Sound, Florida 33455, USA; and **RICHARD M. ENGEMAN**, National Wildlife Research Center, 4101 LaPorte Ave., Fort Collins, Colorado 80521-2154, USA (e-mail: Richard.M.Engeman@aphis.usda.gov).

LEPIDOPHYMA TUXTLAE (Tuxtla Tropical Night Lizard). **PREDATION.** *Lepidophyma tuxtlae* is a viviparous lizard endemic to tropical rain forest in the states of Veracruz, Oaxaca, and Chiapas, México (Bezy and Camarillo 2002. Contrib. Sci. Los Angeles County Mus. 493:1–41). Data on predators of this species are scarce because *L. tuxtlae* is secretive, inhabiting narrow concealed refuges mostly beneath fallen logs, under tree bark and within decaying logs (Castillo-Cerón and López-González 1990. Bull. Maryland Herpetol. Soc. 26:153–158; unpubl. data). Here we describe an observation of predation on *L. tuxtlae*.

At ca. 1400 h on 14 July 2006 during a diurnal herpetofaunal survey, we found an immature wolf spider (prosoma = 8 mm, opisthosoma = 9 mm) of the genus *Hogna* feeding on a neonate *L. tuxtlae* (ca. 28 mm SVL, 35.5 mm tail) beneath the bark of a decaying log. We made this observation in a small fragment of tropical rain forest in the Los Tuxtlas region, Veracruz, Mexico (18°36'6.72"N, 95°08'18.76"W, datum: WGS84, elev. 570 m). The spider held the neonate with its chelicera and the neonate's head and anterior body were partly digested.

Many spiders display opportunistic feeding behavior, and several records exist of spiders feeding on lizards (Corey 1988. J. Arachnol. 16:392–393; Hampton et al. 2004. Herpetol. Rev. 35:269–270); however, our observation represents the first record of predation on night lizards by wolf spiders.

We thank Alejandro Valdez for identifying the spider, and J. Cime for assistance in the field. The *L. tuxtlae* neonate (CNAR 12228) was deposited in Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México.

LEPOSTERNON WUCHERERI (NCN). **VERTEBRATE PREY**. The diet of the Brazilian amphisbaenian *Leposternon wuchereri* is mainly composed of soft items such as oligochaete worms and coleopteran larvae (Barros Filho and Valverde 1996. Sitientibus 14:57–68); ants, termites, beetles, lepidopteran and other insect larvae are the most frequent prey of other amphisbaenians (Kearney 2003. J. Herpetol. 37:379–464). Although amphisbaenians are sometimes fed small vertebrates in captivity (e.g., Gans 1971. Bull. Am. Mus. Nat. His. 144:379–464), consumption of vertebrates in the wild has been rarely demonstrated (e.g., Barbadillo et al. 1998. Herpetol. Rev. 29:236; Colli and Zamboni 1999. Copeia 1999:733–742). Here, we report the first case of *L. wuchereri* feeding on vertebrates.

During faunal rescue at the site of the Santa Clara Hydroelectric power plant, municipalities of Nanuque and Serra dos Aimorés (mean air temperature: 23.1°C), Minas Gerais state, southeastern Brazil (17°53'S, 40°11'W; elev. 105 m), 146 *L. wuchereri* captured were transported to the hydroelectric plant laboratory and kept in a ventilated wooden collection box (40 × 20 × 20 cm) without temperature control for 2–3 days. Wet cotton wads were put in the box to maintain humidity, but the animals were not fed. Animals were subsequently sacrificed, fixed in 10% formalin, placed in a storage solution of 70% alcohol, and deposited at Museu de Ciências Naturais da Pontifícia Universidade Católica de Minas Gerais (MCNR 279–425). During examination of the stomach of an adult (393 mm SVL) female *L. wuchereri* (MCNR 294), we found some small bones (three pterygoids, one ileum, a frontoparietal, two maxillae and a phalange) belonging to anurans and five keratinized claws (probably of some lizard species).

Environmental conditions during flooding of a previously terrestrial area by a new hydroelectric dam represent novel local environmental conditions. As the water floods the area, some animals escape, typically to higher ground, which may cause local and presumably temporary increases in species densities. This has the potential to either decrease food availability or increase competition, and may force individuals to feed on atypical prey. Many unpublished observations indicate that, when crowded in a captive environment, amphisbaenians bite one another and larger individuals eat smaller ones (Gans 1966. Bull. Am. Mus. Nat. Hist. 134:185–260). Our data might indicate that *L. wuchereri* is capable of varying its food habits under such unusual circumstances. If so, the species may be a generalist-opportunist as has already been suggested for other amphisbaenians (Cabrera and Merlini 1990. Herpetol. Rev. 21:53–54).

We thank Ronald Carvalho Júnior for methodological information.

LIOLAEMUS CHACOENSIS (NCN). **BODY TEMPERATURE.** *Liolaemus chacoensis* is an oviparous lizard that inhabits entangled thorny vegetation in the forested landscapes of Chaco Phytogeographic Province, northeastern Argentina (Cabrera and Willink 1980. Biogeografía de América Latina. O.E.A.Washington D.C. 109 pp.). It can maneuver nimbly among well-armed cacti, such as *Opuntia sulphurea*, that hinder its capture. Limited study has addressed its reproduction (Cruz and Ramírez Pinilla 1996. Rev. Española Herpetol. 10:33–39), but data are lacking on its thermal ecology. Here, we present preliminary data on *L. chacoensis* thermal ecology.

On 25 February 2006, we conducted field work in Las Tumanas, Departmento Valle Fértil, San Juan Province (30°52'S, 67°19'W, datum: WGS84; elev. 750 m). Data are based on 11 captures (7 females and 4 males) obtained from randomized visits to shrubs and cacti across the study site. Each individual was captured by noosing. For each capture, cloacal (T_c), substrate (T_s) and air (T_a) were measured (to nearest 0.1°C) with a digital Barnant thermometer. We took T_s at the precise point where an animal was first sighted and T_a 1 cm above the substrate, both immediately following captures. We also recorded microhabitat type (as barren substrate or vegetation litter) for each capture. Individuals were

sacrificed and fixed in the field with 10% formalin. Afterward, SVL was measured (to nearest 0.02 mm).

Mean body temperature of the 11 adult *L. chacoensis* was 33.3°C (SD = 4.0°C). No significant differences were found between the sexes ($F_{1,9} = 0.2$, $P = 0.9$). Body size was unrelated to T_c (Spearman Rank correlation: $r_s = 0.21$, $P = 0.66$). An ANOVA revealed significant differences between T_c and T_a ($F_{1,20} = 6.72$, $P = 0.01$). In contrast, neither T_c nor T_s ($F_{1,20} = 0.04$, $P = 0.84$) or T_a and T_s ($F_{1,20} = 2.83$, $P = 0.10$) differed significantly from one another. Cloacal temperature and each of T_s and T_a were correlated (Spearman Rank correlation: T_s: $r_s = 0.75$, $P = 0.006$; T_a: $r_s = 0.87$, $P = 0.0004$). We found no significant differences in temperature between the two habitat type (Chi-square: $\chi^2 = 0.81$; df = 1; $P = 0.36$).

Based on correlations among T_c, T_s and T_a, thermoregulation in *L. chacoensis* is similar to that in *L. olongasta* (Cánovas et al. 2001. Herpetol. Rev. 37:88), *L. wiegmanni* (Martori et al. 1998. Rev. Española Herpetol. 12:19–26), *L. koslowsky* (Martori et al. 2002. Cuad. Herpetol. 1:78–99), *L. sanjuanensis* (Acosta et al. 2004. Herpetol. Rev. 35:171), and *L.* cf. *elongatus* (Acosta et al. 2006. Herpetol. Rev. 37:466–467), which show a stronger relationship between T_c and T_a. In contrast, *L. pseudoanomalus* (Villavicencio et al. 2007. Amphibia-Reptilia 28:163–165) and *L. elongatus* (Ibargüengoytía and Cussac. 2002. Herpetol. J. 12:131–134) show a more significant correlation between T_c and T_s. Our analysis suggests that *L. chacoensis* is heliothermic and moves among microhabitats to thermoregulate.

LIOLAEMUS DARWINII (NCN). **CANNIBALISM.** *Liolaemus darwinii* is a medium-sized liolaemid lizard of arid western Argentina. Males of this species are territorial (Cei 1986. Reptiles del Centro, Centro-oeste y Sur de la Argentina. Herpetofauna de Zonas Áridas y Semiáridas. Monografie IV, Museo Regionale di Scienze Naturali, Torino, Italy. 527 pp.). Some aspects of their diet, known to include insects, have been described (Avila and Acosta 1993. Facena 10:57–61; De Viana et al. 1994. Rev. Biol. Tropical 42:379–381; Videla 1983. Deserta 7:192–202). Here, we report an observation of cannibalism by an adult male *L. darwinii* on a hatchling.

In February 2001, we collected lizards at Médanos Grandes, Caucete in San Juan Province, Argentina (31°11'S, 68°10'W; elev. 600 m) during an ecological study of this species. Examination of the stomach contents of an adult (54 mm SVL) male *L. darwinii* revealed a hatchling (25 mm SVL) conspecific, and some ants and other Hymenoptera.

Cannibalism has been documented in two other species of *Liolaemus* (*L. koslowskyi*: Avila and Belver 2000. Herpetol. Rev. 31:174; *L. petrophilus*: Avila and Morando 2002. Herpetol. Rev. 33:52). The relative importance of cannibalism in *Liolaemus* population dynamics remains to be investigated.

Specimens (MCN-UNSJ 1845a and 1845b) were deposited in the Herpetological Collection of the Instituto y Museo de Ciencias Naturales de la Universidad Nacional de San Juan (MCN-UNSJ).

NOROPS HUMILIS (Ground Anole). **INTERSPECIFIC INTERACTION.** Aggressive interactions among organisms exhibit a gradient of intensity and frequency depending on how related participating individuals may be. Interactions between conspecifics are usually more intense and more frequent than those between congeners. Aggressive contacts among species of different taxonomic classes, not taking into account predator/prey interactions, are infrequent. These interactions can arise because of interference or exploitative competition (Shields and Bildstein 1979. Ecology 60:468–474), mistaken identification (Hess and Losos 1991. J. Herpetol. 25:256–259), or interspecific territoriality (Robinson and Terborgh 1995. J. Anim. Ecol. 64:1–11).

At 1215 h on 10 August 2006 in Pacuare-Matina Forestry Reserve, Limón Province, eastern Costa Rica (10°12'31.5"N, 83°15'57.2"W, datum: WGS84; elev. 3 m), we observed an adult male *N. humilis* (ca. 37 mm SVL) on a branch 54 cm above the ground. The male perched on the branch for ~90 min, and then jumped to a horizontal stem and did several dewlap extensions, some accompanied with headbobs. We attemped to locate another *N. humilis* nearby, but found none. After a few minutes of remaining immobile, the male ran down the stem and approached a Strawberry Poison-dart Frog, *Dendrobates pumilio*, that was hopping upon a log about 1.5 m away. The lizard initiated a new series of dewlap extensions and headbobs every time the frog hopped, and after these displays the frog stopped and raised its body on its four legs, remained in this position without movement for a few seconds and moved again. Both individuals repeated these interactions for around 10 min until the frog finally jumped away from the log and disappeared behind some bushes.

Whether the interactions we describe resulted from competition, mistaken identification, or interspecific territoriality is unclear. The substantial difference in body shape between *N. humilis* and *D. pumilio* may make mistaken identification less likely than the other possibilities. Likewise, competition and interspecific territoriality could reflect the same intensity of behavior if a limiting resource, such as space, exists, and both species occur at high densities. Both species inhabit primarily the forest floor, are highly territorial, and exhibit high densities where we made our observations. Males *N. humilis* have been reported to spend ca. 20% of their time defending their territories (Talbot 1979. Copeia 1979:472–481), and aggressive contacts among *D. pumilio* conspecifics are frequent in habitats where they reach high densities (Pröhl 1997. Amphibia-Reptilia 18:437–442).

Observations were made during MDB's master's thesis fieldwork. We acknowledge Pacuare-Matina staff for support, and thank Pablo Allen for suggestions.

BARQUERO** (e-mail: marco@biologia.ucr.ac.cr) and **VIVIANA ARGUEDAS (**e-mail: varguedas@biologia.ucr.ac.cr), Asociación para la Conservación y Estudio de la Biodiversidad (ACEBIO), Barrio Los Abogados, Zapote, San José, Costa Rica, and School of Biology, University of Costa Rica.

NOROPS POLYLEPIS (NCN). **PREDATION.** *Norops polylepis*, a denizen of lowland and premontane tropical forests in southwestern Costa Rica and Panama (Savage 2002. The Amphibians and Reptiles of Costa Rica, University of Chicago, Chicago, Illinois. 934 pp.), is known to be preyed upon by several birds, larger lizards, and snakes (Andrews 1983. *In* D. H. Janzen [ed.], Costa Rican Natural History, pp. 409–410. University of Chicago Press, Chicago, Illinois). Here, I report observations of an insect predator of *N. polylepis*.

At 2050 h on 27 May 2005, I observed a female Spear Bearer Katydid (*Copiphora cultricornis*) eating a *N. polylepis* as it perched on vegetation over the Quebrada Agua Buena in Rincon, Costa Rica (8°42'12"N, 83°31'13"W; datum: WGS84; elev. 238 m). The narrow, rocky stream (ca. 3 m in width) was located in lowland tropical wet forest (Holdridge 1967. Life Zone Ecology [revised ed.]. Tropical Science Center, San Jose, Costa Rica. 206 pp.). The katydid was perched upside-down on a small branch (ca. 2 m above the stream), with the body of the anole oriented upright and its anterior end grasped by the katydid's front legs (Fig. 1). When first encountered, the head of the anole was missing, apparently it had been eaten. Over the 10 min of observation, the katydid continued to consume the anole from head to tail. *Copiphora* katydids are known to feed on diverse items including seeds, fruits, and insects (Naskrecki 2000. Katydids of Costa Rica, Vol. 1. Orthopterist's Society, Philadelphia, Pennsylvania. 164 pp.). A congener, *C. rhinoceros*, has been observed feeding on snails and *Norops* sp., but this is apparently the first record of *C. cultricornis* preying on a vertebrate.

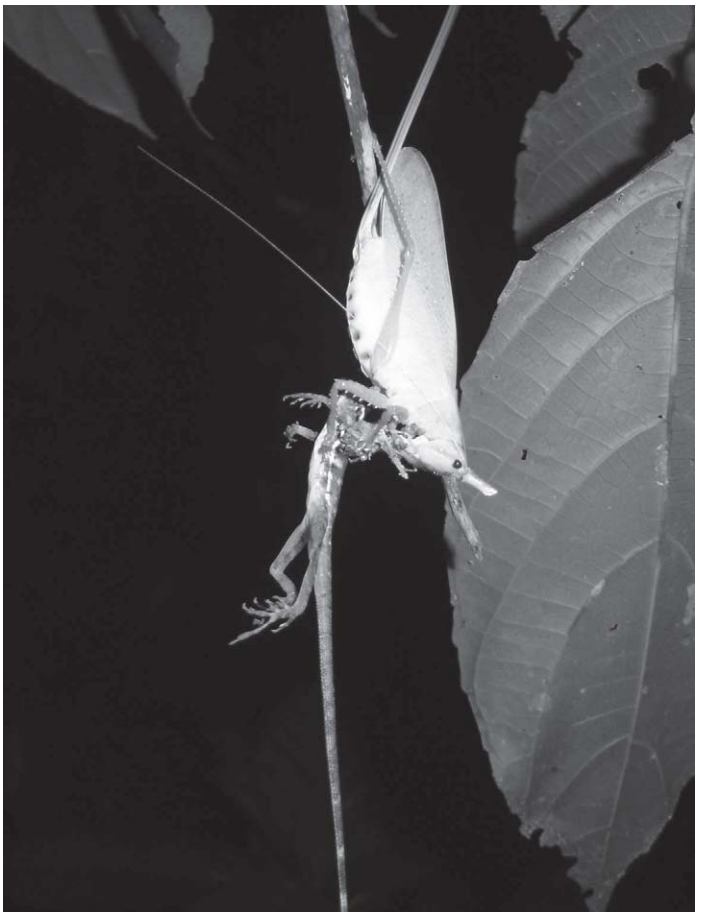

FIG. 1. A katydid (*Copiphora cultricornis*) eating a *Norops polylepis* along the Quebrada Agua Buena in Rincon, Costa Rica.

I thank P. Naskrecki for identifying the katydid and for thoughtful suggestions, and C. Goldberg and D. B. Macotelo for help in the field.

OEDURA RETICULATA (Reticulated Velvet Gecko). **PREDATION**. During an ecological and genetic study of the arboreal gecko *Oedura reticulata* in the Western Australian wheatbelt (between Kellerberrin and Trayning), I recorded two occasions of predation on the species by the Australian huntsman spider, *Isopeda* cf. *magna*. Observations were made in a 1-ha habitat remnant (31°18'S, 117°42'E; elev. 323 m) on *Eucalyptus salubris*, the tree species *O. reticulata* is thought to most prefer. At the first observation at 2320 h on 1 February 2006, the prey, a subadult *O. reticulata* (ca. 50 mm SVL; Sarre 1995. Austral. J. Ecol. 20:288°298), was found already dead. I made the second observation at 0114 h on 10 February 2006, after I released a gecko on its tree of capture. The attacked individual was an adult male (63 mm SVL). After releasing the gecko on one side of the tree, the spider, which had been sitting on the opposite side of the tree trunk, ran along the tree's surface and attacked the gecko. The gecko shed its tail and managed to escape. The *I.* cf. *magna* did not pursue the escaping gecko, but held onto the tail. Both spiders were adults, ca. 50 mm in body length (without legs).

Excluding potentially artificial encounters in pitfall traps (Bauer 1990. Herpetol. Rev. 21:83–87), predation by arachnids is thought to be common among geckos, but few observations exist from the wild. In particular, few reports exist of arboreal geckos as huntsman spider prey. For the arboreal species *Gehyra variegata*, an unsuccesful predation attempt by another species of Australian huntsman spider, *Holconia immanis*, has been recorded in Kinchega National Park, Western New South Wales (Henle 1993. J. Arachnol. 21:153–155).

I thank Julianne Waldock (Western Australian Museum) for identifying the spider, and Klaus Henle and Marion Höhn for reviewing the manuscript.

OPHISAURUS VENTRALIS (Eastern Glass Lizard). **FIRE-INDUCED MORTALITY.** Direct mortality to wildlife due to prescribed fire is of concern to land managers using fire as a manage-

ment tool. The ability of individual animals to escape fire is critical to the long-term survival of species inhabiting fire-maintained systems. Many wildlife species in Florida are both adapted to and dependent upon periodic fire to maintain suitable habitat (Myers and Ewel 1990. Ecosystems of Florida. University of Central Florida Press, Orlando, Florida. 765 pp.). However, species not adapted to survive in pyrogenic landscapes might suffer directly from fire-induced mortality; consequently fire might be a limiting factor. Long-term fire exclusion in many of Florida's forests, habitats that historically burned regularly under natural conditions (lightning ignition), have undergone shifts in vegetation composition, fuel loads (higher), and leaf litter accumulation (higher), essentially altering the vegetative associations (Myers and Ewel, *op. cit.*). Likewise, the suite of wildlife species that inhabit these systems might also shift over time (Myers and Ewel, *op. cit.*). We hypothesize that one such change could favor fossorial species that utilize the litter for cover and foraging. Without normal woodland fire return intervals, non-fire adapted species may be able to augment their populations to a "pseudo-elevated" status resulting in denser populations than were historically present. However, data concerning historical population levels of many species are often lacking and the documentation of wildlife mortality as a result of fire can be difficult.

The benefits of prescribed fire to endangered species and other wildlife in Southeast Florida natural communities are well documented (Myers and Ewel, *op. cit.*), in particular for the many threatened and endangered species found in Savannas Preserve State Park (Marti et al. 2005. Endangered Species Update 22:18–28; Cowan 2005. Endangered Species Update 22:29–39). However, during post-burn evaluations following five prescribed burns and two wildfires, dead Eastern Glass Lizards (*Ophisaurus ventralis*) were observed within three distinct conservation areas in Southeast Florida (including Savannas Preserve) between January 2003 and March 2004. Burned areas were surveyed to characterize the fires and at the same time were canvassed for wildlife mortality. *Ophisaurus ventralis* was the only lizard species for which mortalities were observed. One dead *O. ventralis* was found on each of two prescribed fires conducted at J. W. Corbett Wildlife Management Area, Palm Beach County Florida, on 15–16 January 2003. Burn unit sizes were 14.2 ha and 4.0 ha, respectively. One dead specimen was also observed following a 32.4-ha prescribed burn conducted on the North Fork St. Lucie River Preserve State Park, St. Lucie County Florida on 28 January 2003. On 15 January 2004, search of a 12.1-ha prescribed burn on a separate parcel of land within the boundaries of the same park revealed 8 dead specimens. Three post-burn observations were made at Savannas Preserve State Park, Martin and St. Lucie Counties, Florida. On 26 November 2003 following a 6.1 ha prescribed burn, one dead lizard observed; 30 July 2003 following a 0.8 ha wildfire, one dead lizard observed; and, a single dead lizard was also found following a 87.4-ha wildfire on 22 March 2004. Unlike many other amphibians, reptiles, birds, and mammals in Southeast Florida adapted to and dependent upon fire (Cowan, *op cit.*; Marti et al., *op cit.*), these observations suggest that this species, often associated with dense herbaceous growth, appears susceptible to some level of fire-induced mortality. Therefore, it may be to this species' benefit to apply patchy prescribed burns resulting in a mosaic of burned and unburned areas.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **POTENTIAL DIETARY THREAT.** Seed-harvesting ants of the genus *Pogonomyrmex* are important prey for horned lizards, including *Phrynosoma cornutum* (Pianka and Parker 1975. Copeia 1975:141–162; Sherbrooke 1995. Herpetol. Rev. 26:25–26). These venomous ants pose both biting and stinging threats to feeding lizards (Rissing 1981. Ecology 62:1031–1040; Schmidt et al. 1989. Copeia 1989:603–607). Though the coating of ants with pharyngeal and esophageal mucus secretions (Schmidt et al., *op. cit.*; Schwenk and Sherbrooke 2003. Integr. Comp. Biol. 43:1061; Sherbrooke 2003. Introduction to Horned Lizards of North America, University of California Press, Berkeley. 178 pp.) and blood plasma resistance to ant venom (Schmidt et al., *op. cit.*) provide protection during feeding on *Pogonomyrmex*, ingestion of other noxious invertebrates might not always be successful (Cohen and Cohen 1990. Southwest. Nat. 35:369; Manley and Sherbrooke 2001. Southwest. Nat. 46:221–222; Sherbrooke 2002. Herpetol. Rev. 33:312). Stomach analyses have often reported extraneous (non-food) materials assumed to be inadvertently ingested during feeding (Milne and Milne 1950. Am. Midl. Nat. 44:720-741; Pianka and Parker, *op. cit.*). Nonetheless, *P. cornutum* capture ant prey (Ott et al. 2004. J. Exp. Biol. 207:3067–3072; Ott et al., unpubl. data) using acute vision and split-second control of tongue-tip direction. During capture, ant prey are moved past a horned lizard's teeth without mastication into the esophagus via "pharyngeal packing" (Schwenk 2000. *In* Schwenk [ed.], Feeding : Form, Function and Evolution in Tetrapod Vertebrates, pp. 175–291. Academic Press, San Diego, California; Meyers and Herrel 2005. J. Exp. Biol. 208:113–127). The purpose of this note is to report an observation suggesting that during use of this prey-capture system, *P. cornutum* occasionally ingests items that present a dietary threat, and to note that this threat may be minimized by the lizards during prey selection.

On 2 June 2005, I examined the peritoneal cavity of a juvenile *P. cornutum* (56 mm SVL, 8.8 g) collected 27 May 2005 in Antelope Pass, Peloncillo Mountains, Hidalgo Co., New Mexico (Sherbrooke 2002. Herpetol. Rev. 33:21–24) and discovered an intact 12 mm long, sharply-pointed grass seed with three awns (*Aristida*, perhaps *purpurea*; identification by D. K. Aasen-Rylander and J. Bowers). No wounds were evident and the lizard appeared otherwise healthy, although externally the desiccated head of a *Pogonomyrmex* ant clung by its mandibles to a toe of the lizard.

Captive *P. cornutum* fed *Pogonomyrmex* ants obtained through colony excavation (Sherbrooke 1995, *op. cit.*) often avoid eating workers carrying larvae and pupae inadvertently mixed with unburdened ants (pers. obs.). Similarly, Bott et al. (2001. Herpetol. Rev. 32:41) reported that a *P. cornutum* feeding on alate termites (*Gnathamitermes perplexus*; sex not identified) made no attempt to capture *Pogonomyrmex* ants carrying these same termites. Field observations of a selection of *Pogonomyrmex* ants during feeding by *P. cornutum* (H. Topoff, pers. comm.) and *Phrynosoma solare* (C. May, pers. comm.) also suggest that horned lizards selectively avoid capturing ants carrying seeds. If the seed I found in the peritoneal cavity of the juvenile *P. cornutum* originated with seed-carrying ant prey, my observation suggests that ants carrying seeds are occasionally taken, and the seeds have the potential to penetrate the walls of the digestive tract, thus becoming potentially deleterious to internal organs or tissues.

PHRYNOSOMA DOUGLASII (Pygmy Short-horned Lizard) **MAXIMUM ELEVATION.** St. John (2002. Reptiles of the Northwest: California to Alaska, Rockies to the Coast. Lone Pine Publishing, Auburn, Washington. 272 pp.) and Stebbins (2003. Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 533 pp.) reported a maximum elevation of 1830 m for *Phyrnosoma douglasii*. Here, we report observations that significantly increase known maximum elevation.

During a visit to Hart Mountain National Antelope Refuge, Lake County, Oregon (42°30'06"N, 119°43'11"W, datum: WGS84; 2200 m elev.) between 0945 and 1445 h on 1 July 2006 (air temperatures 25.5–29.5°C), we observed 13 *P. douglasii* (5 adult males [38, 38, 45, 46, and 53 mm SVL], 3 subadult males [33 and 36 mm SVL; one lizard not measured], 2 adult females [51 and 71 mm SVL], and 3 subadult females [35, 38, and 39 mm SVL]) on an unnamed mountain ca. 12 km NNE of Hart Mountain. Lizards were observed over an elevation range between 1910 and 2200 m in shrub-steppe habitat with lithosol terrain dominated by Stiff Sage (*Artemisia rigida*) and on bare dirt trails in grassland habitat with loamy soil terrain dominated by bunchgrasses (*Pseudoroegneria spicata*). Our observations extend the maximum elevation range ca. 370 m above maximum reported by St. John (*op. cit.*) and (Stebbins, *op. cit.*).

We deposited 4 color voucher photographs (BYU 4086–4089) and their associated locality data in the herpetological collection at the Brigham Young University Museum. Jack Sites verified the species identity of the animals.

PODARCIS SICULA (Italian Wall Lizard). **OPPORTUNISTIC FORAGING BEHAVIOR**. Native to southern Europe, *Podarcis sicula* was accidentally introduced to Long Island, New York in 1967 (Gossweiler 1975. Copeia 1975:584–585). Burke and Mercurio (2002. Amer. Midl. Nat. 147:368–375) studied the diet of *P. sicula* on Long Island but only utilized stomach contents; no reports exist of *P. sicula* foraging behavior in the urban-industrialized environment. Here, I describe preliminary observations on *P. sicula* foraging behavior in this environment.

During my investigation of their occurrence along the Long Island Railroad, I made observations of *P. sicula* at the Carle Place train station in Carle Place, New York (40°44'56"N, 73°36'19"W, datum: WGS84; elev. 30 m) between May and July 2006. Vegetation where I made these observations consisted primarily of exotic shrubs (e.g., *Artemisia vulgaris*) and herbaceous annuals and perennials (e.g., *Centaurea* sp.). Ground cover consisted of dead *A. vulgaris* and *Centaurea* stems, and human-generated debris such as bottles, cans, and paper litters much of the ground near the east- and west-bound train platforms.

At 1224 h on 1 June 2006, an adult (ca. 7.0 cm SVL) male *P. sicula*, seen foraging along the edge of an *A. vulgaris* patch, approached an empty aluminum beverage can behind the westbound platform. The lizard stopped beside the can remaining motionless for ca. 45 sec until a small unidentified fly (Diptera) landed on the can. The fly was rapidly seized and consumed, and the lizard proceeded to feed on 4 additional flies attracted to the can over the next 3 min. Shortly afterwards, the lizard returned to the same patch of vegetation along which it was originally seen foraging. About 30 sec after the male retreated, an adult (ca. 6.0 cm SVL) female approached the same can from another nearby patch of vegetation. It then proceeded to feed in the same manner as the male, consuming a house fly (probably *Musca domestica*) and two ants (likely *Tapinoma sessile*) over the course of ca. 2 min before also retreating into the vegetation. On 6 June 2006 at 1147 h, a second adult (ca. 6.4 cm SVL) male was observed feeding on small flies (seemingly the same fly species observed on 1 June 2006) attracted to an empty glass beer bottle located behind the eastbound platform. This lizard consumed three flies as each landed on the bottle, and then moved to a nearby rock where it basked for ca. 2 min before retreating beneath a rock.

Comparative studies have aided in understanding the differences in ecologies between the introduced Long Island and indigenous European *P. sicula* populations (Burke et al. 2002. Copeia 2002:836–842; Burke and Mercurio, *op. cit.*; Burke and Ner, *op. cit.*). In Europe, *P. sicula* occur in both natural and disturbed environments (Foa et al. 1992. Herpetol. J. 2:86–89; Avery 1993. Ethol. Ecol. Evol. 5:511–518), but Italian Wall Lizards in New York are restricted to anthropogenic environments (Burke and Mercurio, *op. cit.*; Burke and Deichsel, *in press* Herpetol. Conserv.). Review of the literature reveals that no reports of opportunistic foraging associated with human-generated debris exist for *P. sicula* or any other *Podarcis*. Further research is needed to determine both how common and how important such behavior is in maintaining *P. sicula* in heavily-disturbed environments.

TEIUS OCULATUS (NCN)**. COURTSHIP; MATING.** *Teius oculatus* is a diurnal, oviparous, insectivorous species (Avila 2002.

Biogeographica 78:15–33) with a broad distribution in eastern and central Argentina, Uruguay, and southeastern Brazil (Cei 1993. Reptiles del Noroeste, Nordeste y Este de la Argentina. Herpetofauna de las Selvas Subtropicales, Puna y Pampas. Museo Regionale di Scienze Naturali, Torino, Italia, Monogr. 14. 949 pp.). Save a brief account by Gudynas et al. (1981. C. E. Don Orione Contr. Biol. Montevideo 8:1–9), courtship and mating are undescribed. Here, we relate behaviors during courtship and mating in both free-ranging and captive *T. oculatus*.

On 10 December 2006, HJPT filmed a free-ranging pair of *T. oculatus* in the National Park Lihue Calel, La Pampa, Argentina (37°55'S, 65°32'W, datum: WGS84; 275 m elev.), and on 5 February 2006, JS filmed a captive pair that came from El Bagual Reserve, Formosa, Argentina (26°10'S, 58°56'W, datum: WGS84; 75 m elev.). The captive pair had been living in a terrarium (70 cm × 30 cm × 30 cm) for about a year when the behaviors we report were first observed. Both were of approximately the same snout–vent lengths, the male being 11.5 cm and the female 10.4 cm long. The male approached the female, climbed on her back and began performing lateral head movements over her neck and head region as if gently rubbing it. The female walked a few steps and occasionally moved her head laterally in unison with the male's back and forth movements. The male also tongue-flicked and did a few "leg strokes" (Carpenter and Ferguson 1977. *In* Gans and Tinkle [eds.], Biology of the Reptilia, Volume 6, pp. 335–403. Academic Press, New York, New York), moving one hind leg up and down the side of the female as if stroking her. After about 3 min, the female lifted her cloacal region. The male immediately grasped the female from the left side of her pelvis, formed an arc around her and introduced the right hemipenis in her cloaca. During mating, the female remained motionless. After about 19 min, the pair abruptly disengaged, apparently initiated by the female who took refuge in their common shelter. Meanwhile, the male dragged his cloacal region with hind legs extended in an apparent attempt to reintroduce the everted hemipenis. In October 2006, the same pair was observed mating a second time. On this occasion, we did not observe courtship prior to mating.

We observed a similar sequence of behaviors in the free-living pair. The main difference seemed to be the apparent inexperience of the male. In this case, the male was about 8 cm in snout-vent length and the female 10 cm. The male was possibly a subadult (the pair was not captured to confirm). Although this male performed the same behaviors observed in the captive male, he appeared more animated, moving about the female erratically. While performing the lateral head movements as well as trying to gain a position over the female's back, he seemed to be slipping off so that the behavior was done over different parts of her back as well as over her head as he turned around several times, front and back, looking for the right position. This lasted about 3.5 min. The male then did a few leg strokes over her tail, turned around, and resumed the lateral head movements for about 30 sec, after which he seized her by the pelvic region, in this case from the right. A little less than 2 min later, the female disengaged and ran off as the male followed her for 4–5 m. At that moment, another, larger (11 cm SVL), brightly colored male, appeared. The two males started fighting. During the struggle, which did not last more than 2 sec, the two males stood up on their hind legs, facing each other, apparently wrestling with their anterior limbs (the latter was not filmed). Following this short quarrel, the smaller male quickly retreated, disappearing into the bush. The larger male then started looking for the female but they were soon lost from our sight.

Mating behavior we observed in *T. oculatus* was similar to that reported by Gudynas et al. (1981, *op. cit.*), i.e., the male grasping the female by the trunk and forming an arc around her. However, these authors did not observe courtship. Instead, males ran persistently after a female until seizing her. When mating was over, the authors also observed the male drag the cloacal region, hind legs extended, thus reintroducing the everted hemipenis. Other examples of lateral rubbing of the neck or head of female as part of courtship in lizards were not found in the literature, though Carpenter and Ferguson (*op. cit.*) described a behavior called "head press" or "jaw rub" as "rubbing or pressing of the chin or head region against another individual, usually associated with courtship or copulation," but specific examples were not provided. On the other hand, leg strokes have been reported in *Tupinambis teguixin* and in *T. rufescens* (Chani 1988. Proyecto *Tupinambis*: Estado de las investigaciones hasta la primavera de 1988. Comportamiento. III Congreso de Producción, Industrialización y Comercialización de la Fauna; Federación Argentina de la Comercialización e Industrialización de la Fauna, Bs.As.) and in some skinks and anguids (Carpenter 1978. *In* Greenberg and MacLean [eds.], Behavior and Neurology of Lizards, pp. 253–267. NIMH, Rockville, Maryland).

We thank Gustavo Scrocchi for comments on the manuscript, the Dirección de Fauna de Formosa and Alejandro Di Giacomo, Aves Argentinas & Alparamis SA for allowing us to collect animals in El Bagual Reserve; the Dirección of National Park Lihue Calele, la Pampa, for letting us film animals; and PIP-CONICET 5780, and CIUNT G315 for financial support.

TRETIOSCINCUS BIFASCIATUS (Limpia Casas). **DIET.** *Tretioscincus bifasciatus*, a diurnal gymnopthalmid lizard known from northern and central Colombia and northern Venezuela, inhabits a variety of life zones from dry to moist Tropical and Premontane forests over a broad altitudinal range (sea level to 1500 m; S. Ayala and F. Castro, unpubl. data). Most often observed in sunny patches near the base of large trees or in nearby litter, it can also be found under brush in open areas or on rocks in deforested sites, but always near a large tree or dense vegetation. It seems most active during sunny intervals, but almost nothing is known of its ecology. Here, we provide preliminary data on its diet from central Colombia.

We studied 32 *T. bifasciatus* from the Inspección de Policía Guadualito, Municipality of Yacopí, Departamento Cundinamarca (74°18'W, 5°37'N, elev. 800–1100 m) over the interval February 1998–January 1999). The area, on the Cordillera Oriental of the Colombian Andes, is located on steep slopes draining to the

Magdalena Valley. Highly human-altered, forest fragments occur only at the top of the mountains; sugar, corn, and casaba plantations, and cattle pastures occur on the slopes. The lizards were most often found in sunny spots on the palm thatch roofs of the sugar mills (''trapiches'') (37.5%), or in the nearby litter close to the "trapiches" (25%), or near the base of large trees (15.6%), other individuals were seen on fallen trunks (12.5%), and inside or around abandoned rural houses (9.4%).

We examined the stomachs of 24 lizards by dissection. Eleven *T. bifasciatus* had food remnants in their stomachs; the remaining 13 lizards had empty stomachs. The high number of lizards with empty stomachs seems unrelated to foraging interval because the lizards were randomly collected at different times. Food found in the stomachs was exclusively cockroaches, spiders and grasshoppers; no plant material was found. Cockroaches were the most important prey, based on numbers (N = 7, 41.8%), volume (1763 mm^3, 50.2%), and frequency with which prey was recorded among lizards with food (N = 6, 54.5%). Grasshoppers (N = 4, 23.5%) followed cockroaches in volume (1336 mm^3, 38%) and frequency (N = 4, 36.4%). Prey volume of spiders (N = 6, 35.3%) was the least among three prey groups (414 mm, 11.8%) but was in similar frequency to grasshoppers (N = 4, 36.4%).

Tretioscincus bifasciatus are sympatric and synoptic with *Mabuya* sp. We recorded 15 prey species from 89 *Mabuya* sp. (unpubl. data), but the same three prey groups were dominant (70% of individual prey) implying that these prey taxa are generally availability to both lizards.

We thank the residents of the Inspección de Policía de Guadualito, especially Elsa de Alvarez and her family, for their hospitality and collaboration during our field trip.

TROPIDURUS TORQUATUS (Brazilian Collared Lizard). **DIET**. *Tropidurus torquatus* is an ambush forager that feeds mainly on arthropods, but may also eat some plant material, e.g., seeds, flowers and leaves (Bergallo and Rocha 1994. Austral. J. Ecol. 19:72–75; Teixeira and Giovanelli 1999. Rev. Brasileira Biol. 59:11–18). Vertebrate prey is poorly documented though *T. torquatus* is known to consume smaller lizards (Araújo 1991. Rev. Brasileira Biol. 51:857–865; Teixeira and Giovanelli, *op. cit.*).

On 10 April 2006, we observed a *T. torquatus* eating a juvenile rodent, probably *Rattus rattus*. The rodent, which was being eaten head first, had only its tail and a hind limb outside the tropidurid´s mouth. The *T. torquatus* specimen, clearly a large (ca. 10 cm SVL) adult male, could not be captured for more accurate measurement, though photographs were taken before the lizard fled. The observation was made at Praia do Canto, Vitória, Espírito Santo, Brazil (20°18'13"S, 40°17'46"W, datum: Córrego Alegre SAT 69; elev. near sea level).

Inclusion of small mammals in the diet of *T. torquatus* reinforces the idea that this species is an opportunistic and dietary generalist. Males grow larger than females and it has been suggested that larger individuals ingest larger prey (Van Sluys et al. 2004. J. Herpetol. 38:606–611). For that reason, though both males and females are reported to feed upon vertebrates, males may consume larger vertebrates (e.g., rodents) more frequently, though this assumption remains to be adequately tested.

We thank C. F. D. Rocha for comments on the manuscript. Conselho Nacional de Desenvolvimento Científico e Tecnológico for financial support to PLP.

TROPIDURUS TORQUATUS (Lagartixa, Collared Lizard). **TAIL AS FOOD**. *Tropidurus torquatus* is a common iguanid lizard ranging from Brazil to Argentina that inhabits the Cerrado and Atlantic Forest domains in Brazil (Rodrigues 1987. Arq. Zool. 31:105–230). Though widely distributed and abundant, few records of predators on *T. torquatus* exist; we known of only one record of predation, involving a Burrowing Owl, *Speotyto cunicularia* (Kokubum and Zacca 2004. Herpetol. Rev. 35:270). This note describes the first observation of a harvestman (an opilionid arachnid) feeding on the tail of the lizard, *T. torquatus*.

At night on 8 November 2005, JC observed a female harvestman, *Gonyleptes* sp. nov. (Opiliones, Gonyleptidae, dorsal scute length 7.4 mm), eating a tail (66 mm long) of a *Tropidurus torquatus* at the Parque Nacional do Caparaó, Santa Marta district, Ibitirama municipality, State of Espírito Santo, Brazil (20°29'40"S, 41°44'00"W; elev. ca. 960 m). The harvestman was located head down, ca. 50 cm above ground level on a wall inside an abandoned house surrounded by relatively undisturbed forest, with its chelicerae and pedipalps holding the basal portion of the lizard's tail. One vertebral bone in the tail was visible, the tissues around it presumably having been swallowed by the harvestman, and about 0.6 mm of the tail was partially digested.

Harvestmen are omnivorous arachnids that prey chiefly on small invertebrates (Acosta and Machado, *in press*. *In* Pinto-da-Rocha et al. [eds.], The Harvestmen: The Biology of Opiliones. Harvard University Press, Cambridge, Massachusetts). With the exception of two records of feeding on frog metamorphs (Castanho and Pinto-da-Rocha 2005. Rev. Ibérica Aracnol. 11:43–45), only dead vertebrates have been recorded as food items (Acosta and Machado, *op. cit.*). Nevertheless, we stress that diet items are known for only about 40 of the ca. 6000 known species of harvestmen. The harvestman encountering the tail of this lizard was not recorded. However, the harvestman probably did not remove the tail from a live lizard as it would not strong enough to do so; more likely, it was found opportunistically. This observation represents a new item in the diet of harvestmen in general.

We know of one other instance of a harvestman feeding on a lizard tail. A picture (online at: http://commons.wikimedia.org/wiki/Image:Harvestman_eating_skink_tail.jpg) shot by Tim McCormack in Virginia (USA) shows a skink tail (identified as that of a *Eumeces fasciatus*) being eaten by a *Leiobunum* sp., a sclerosomatid opilione.

Vouchers of the harvestman and lizard tail (MZUSP-26.836) were deposited at the Museu de Zoologia da Universidade de São Paulo, State of São Paulo, Brazil. We are grateful to Glauco Machado (UNICAMP) for making us aware of the internet photo. We thank the Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA, license number 030/2005 – CGFAU/LIC) and Estêvão José Marchesini Fonseca, director of the Parque Nacional do Caparaó, for lodging facilities during our stays in the park and for permission to work there. We thank Felipe Franco Curcio for photographic assistance, and M. P. Hayes and an anonymous reviewer for editorial assistance.

UTA STANSBURIANA (Side-Blotched Lizard). **MORTALITY**. Many reports of human-induced mortality exist among vertebrates (mammals: Karraker 2001. Wildl. Soc. Bull. 29:1158–1162; amphibians: DiMauro and Hunter. 2002. Forest Sci. 48:397–406; turtles: Barko et al. 2004. J. Wildl. Manage. 68:1145–1150). Here, I add to the data describing instances of mortality with observations made at a water pipe cover in eastern New Mexico.

My observations were made during fieldwork on 20 June 2003, within the city limits of Fort Sumner, De Baca County (34°28'26"N, 104°14'22"W; elev. 1250 m). A slightly ajar water pipe lid used to cover a valve for a water line was removed to reveal a trapped (but living) adult *Uta stansburiana*. This partially buried pipe has an inner diameter of 45 cm and is 38 cm deep. The lizard was captured, photographed, then released. This individual seemed healthy, suggesting it was recently trapped. Further investigation revealed 9 skulls and other bones at the bottom of this pipe. After closing the pipe lid, I rechecked it on 23 June 2003, 15 and 17 August 2003, 17 and 21 June 2004, and 10 August 2004; no additional animals or bones were found.

Four of the five lizard skulls were adult *U. stansburian*a, an abundant species throughout New Mexico (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque. 431 pp.). The fifth skull was that of an adult Great Plains Skink, *Eumeces obsoletus*. Except for the *E. obsoletus* skull, little to no flesh remained on the skulls. The four remaining skulls were identified as *Reithrodontomys* sp. (two species, *R. megalotis* [Western Harvest Mouse] or *R. montanus* [Plains Harvest Mouse], are possible at this locality [Burt and Grossenheider 1980. A Field Guide to the Mammals: Field Marks of All North American Species Found North of the Mexican Boundary. Houghton Mifflin Co., Boston, Massachusetts. 289 pp.]).

Water pipes of the kind I describe can unquestionably trap small vertebrates, including *U. stansburiana* and *Reithrodontomys* spp. Trapped individuals might have attempted to escape the heat of the day or night cold; if true, this example represents an "ecological trap" (Schlaepfer et al. 2002. Trends Ecol. Evol. 17:474–480). Skulls and bones mostly lacking flesh implies that the water pipe cover had been ajar for some time. No mortality was observed after the pipe lid was properly closed. Hence, similar to standard pitfall traps, water pipe lids should always be snugly closed when not in use if no mechanism exists to allow escape of trapped animals.

SERPENTES

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). **ACTIVITY**. The ecology of *Agkistrodon piscivorus leucostoma* is poorly understood, relative to western subspecies. For example, most studies of home range and activity patterns have been conducted on subspecies other than *A. p. leucostoma* (Dundee and Burger 1948. Chicago Acad. Sci. 21:1–2; Wharton 1969. Bull. Florida State Mus. 14:227–272; Kofron 1978. J. Herpetol. 12:543–554; Martin 1982. Home range, movements, and activity patterns of the cottonmouth, *Agkistrodon piscivorus*, in southern Louisiana. M.S. Thesis, Univ. of Southwestern Louisiana, Lafayette. 53 pp.; Cook 1983. Activity patterns of the cottonmouth water moccasin, *Agkistrodon piscivorus* Lacepede, on a northwest Florida headwater stream. M.S. Thesis, Univ. Florida, Gainesville, Florida. 88 pp.; Sexton et al. 1992. *In* Campbell and Brodie [eds.], Biology of Pitvipers, pp. 337–345. Selva, Tyler, Texas). Kofron (*op. cit.*) noted that *A. p. subspecies* moved up to 80 m way from water. Martin (*op. cit.*) found that between May and October, *A. piscivorus* in southern Louisiana moved an average of several meters a day, usually immediately after dusk, and concluded they were both crepuscular and nocturnal.

Here, we characterize movements and activity ranges of six radio-tagged *A. p. leucostoma* (two males and four females; 55–85 cm SVL, 150–480 g) between July 1993 and January 1994 in the Ouachita National Forest (Montgomery County, Brier Creek, Arkansas). We recorded 272 observations for all snakes (30–51 observations/snake). Total distance traveled by each individual ranged from 468–827 m (mean = 604 m). Three females exhibited noncontiguous summer and fall activity ranges. The number of meters moved per day (mean = 8.0 m, range = 0.5–14.0) significantly differed between months (Kruskal-Wallis, $H = 21.07$, $p<0.01$), with the greatest movement occurring in October. Activity ranges (convex polygon) ranged from 0.13–1.14 ha (mean = 0.45 ha).

Our radio-tagged snakes were found 7% of the time in the creek, 17% within 1 m of the creek, 52% within 5 m, and 75% within 10 m. The mean distance from water (excluding snakes found in the water) for all six snakes was 10.7 m. Proximity to the creek (or associated bodies of water) did not significantly differ between males and females (Kruskal-Wallis, $H = 0.02$, $p = 0.88$), but did significantly differ by month (Kruskal-Wallis, $H = 33.6$, $p<0.01$). The farthest-ranging *A. piscivorus* was a female found 85 m from water. Most Brier Creek cottonmouths showed increased frequency of movement during the fall return to their hibernacula. *Agkistrodon piscivorus* were relatively sedentary overall; the greatest distances

moved occurred during October and averaged only 8 m/day. Movement ranges reported from Louisiana cottonmouths indicated distances of 10 m or more every night during summer periods and the beginning of a return to hibernacula in late November (Martin, *op. cit.*).

Three of the six snakes (two males and a female) migrated to a den site outside of their summer/fall activity range. The greatest distance moved from a location in a summer activity area to a den site was 436 m. All den sites were located within 10 m of Brier Creek or a tributary. Hibernacula were located in rocky outcroppings high on streamside banks, occasionally under embedded boulders. These habitats are superficially similar to rocky hillside hibernacula described for northern populations (Neill 1947. Herpetologica 3:203–205; Barbour 1956. Trans. Kentucky Acad. Sci. 17:31–41; Burkett 1966. Publ. Univ. Kansas Mus. Nat. Hist. 17:435–491). Four of the cottonmouths were periodically observed (1–3 times each) on the surface at the den site during the winter.

ARRHYTON EXIGUUM (Puerto Rican Garden Snake). **REPRODUCTION**. I witnessed two adult *Arrhyton exiguum* engaged in what appeared to be courtship behaviors at 1240 h on 6 March 2007 in pastureland in the Río Grande region of northeastern Puerto Rico. The two snakes were entwined, but were not moving when first sighted. One individual appeared to be larger than the other. However, no chin rubbing, tongue-flicking, or aggressive behaviors were observed. I could not ascertain whether the male's hemipenes was intromitted without disturbing the snakes. The habitat consists of moist, clay-like soils with little vegetation cover, though the snakes were between small shrubs when observed. Ambient temperature at the time of observation was approximately 27.2°C, with both individuals exposed to sunlight. When encountered, the two individuals fled (still entwined) under a nearby piece of aluminum. To my knowledge, this is the first observation of reproductive behavior in Puerto Rico or any other West Indian location.

Submitted by **CHRISTOPHER BLAIR**, Department of Natural History, Royal Ontario Museum, 100 Queen's Park, Toronto, Ontario, Canada M5S 2C6; e-mail: Christopher.blair@utoronto.ca.

CORALLUS COOKII (St. Vincent Treeboa). **FORAGING**. *Corallus cookii* is endemic to the Lesser Antillean (West Indies) island of St. Vincent, where it is widespread in a variety of habitats (including some that are dramatically altered) from sea level to at least 425 m (Henderson 2002. Neotropical Treeboas: Natural History of the *Corallus hortulanus* Complex. Krieger Publ. Co., Malabar, Florida. 197 pp.). Its diet is comprised of *Anolis* lizards and introduced rodents (*Mus* and *Rattus*), but specific details of foraging behavior are unknown, although young boas are known to be active foragers and large adults are ambush strategists (Henderson, *op. cit.*).

On 6 June 2006, we observed a *C. cookii* (~ 755 mm SVL) stalk and capture an adult *Anolis trinitatis* at Ferret (St. Patrick Parish: 13.212°N, 61.251°W, datum WGS84; ~160 m elev.), an area of mixed agriculture and secondary forest. When first noticed (at 2220 h), the boa was at 2.0 m in a tree of undetermined species, about 15 cm from the sleeping lizard, approaching slowly from behind and slightly above it. As we did not want to disturb the boa, we only intermittently used diffuse light from a headlamp to monitor the snake's progress, and therefore were unable to determine whether or not the boa exhibited tongue-flicks. By 2230 h, the snake was within 2.0 cm of the anole and, for the next 15 min, movement by the boa was almost imperceptible. The *C. cookii* was virtually touching the anole before it grabbed it in the nuchal region, commenced to throw a coil around it, and subdue it. The stealthy manner in which the boa approached the anole, especially the almost imperceptible movement over the last 2.0 cm, closely parallels the foraging behavior of *C. grenadensis* on Grenada, a closely related species in which foraging behavior has been studied in some detail (Yorks et al. 2003. Stud. Neotrop. Fauna Environ. 38:167–172). At 2256 h, upon completion of swallowing the lizard, the boa ascended into the crown of the tree.

Fieldwork in St. Vincent was funded by a grant (DBI-0242589) from the National Science Foundation (USA) to Robert Powell.

ENULIUS SCLATERI (White-headed Snake). **REPRODUCTION.** *Enulius sclateri* is an uncommon, neotropical, and fossorial amastidine colubrid (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. University of Chicago Press, Chicago. 954 pp.). Here we provide the first report of basic reproductive ecology in the wild.

On 09 May 2004 a torrential tropical storm caused a 25-m tall *Cordia alliodora* (Boraginaceae) tree to fall in the laboratory clearing of the La Selva Biological Station (Heredia, Costa Rica: 10.4327°N, 84.0080°W, 35 m elev.). Within 12 h of treefall, CLC excavated a tree hollow (ca. 10 cm deep and 16.4 m from the base of the tree) uncovering 5 nearly equivalent-sized snake eggs, later determined to be *E. sclateri*. The temperature of the canopy soil under the eggs was 24.8°C. Two eggs were punctured and no embryo present, possibly from predation. The three remaining eggs, adhered together along the longitudinal axis, were brought into the laboratory for size and weight measurements using calipers and a 5 g Pesola scale. On 09 May the three eggs measured 22.8 mm × 9.2 mm, 21.8 mm × 9.7 mm, and 21.1 mm × 8.6 mm, and all weighed exactly 3.6 g. The eggs were incubated in ambient outdoor conditions until they hatched. On 18 June 2004, a fungus infected one egg, but the hatchling actively emerged as we attempted to extract it from the egg. The other two hatchlings

emerged on 23 and 25 June. Upon hatching, the snakes were identified to species, measured, and weighed using a digital electronic balance. The hatchlings exhibited the same pattern and coloration as adults of this species. The unfed 11-day old hatchlings measured 89, 92, and 90 mm SVL, 58, 57, and 56 mm tail length, and weighed 0.79, 0.74, and 0.65 g. All three snakes were released on 27 June at the site of the treefall.

This observation is the first known record of arboreal oviposition by a species commonly believed to be solely fossorial, providing evidence that some fossorial species use tree hollows and canopy soil on branches of trees in the third dimension of the forest. Facultative use of arboreal habitats has been described for other presumably "terrestrial" or "fossorial" snake species for foraging (Keller and Heske 2000. J. Herpetol. 34:558–564) and/or unknown reasons (Stidham 2001. Herpetol. Rev. 32:262) but thus far none has confirmed reproductive behavior in the canopy habitat.

There are two possible explanations for our observation. First, *E. sclateri* oviposition site depends on the drier more exposed microenvironment found in the canopy compared to the forest floor, or second, despite differences between canopy and forest floor habitats, the structural similarities are sufficient to make canopy oviposition desirable for *E. sclateri.* Predator or prey interactions likely underlie arboreal oviposition: deep tree holes or cover by canopy soil shield the eggs from potential predators, or place adults and/or hatchlings near a potential food source. Our observation confirms that some species are using a much larger range of forest microhabitats than previously considered. This observation of a putatively 'fossorial' snake ovipositing in the canopy is evidence that facultative use of arboreal habitats may be more widespread than commonly thought.

We thank H. W. Greene, the Mellon Foundation, the Organization for Tropical Studies, the National Science Foundation, and the Ministry of Environment and Energy (Costa Rica) for assistance and support.

HETERODON SIMUS (Southern Hognose Snake). **HIBERNACULA.** The natural history of *Heterodon simus* is poorly known (Tuberville et al. 2000. J. Elisha Mitchell Sci. Soc. 116:19–40) and hibernacula have not been described. Between 11 October 1998 and 18 February 2006, we radio tracked three adult male and three adult female *H. simus* through a single winter each, and one adult female through two consecutive winters, in upland sandhill habitats (Scotland County, North Carolina, USA). In all cases (N = 8), the snakes essentially excavated their own hibernacula, burrowing more or less vertically into sandy soil in inconspicuous spots. No obvious stump holes or other existing underground chambers were used, and entrance and exit holes were usually not visible after a few days. One male over-wintered in the road bank of a state maintained sand road (ca. 2 m from the edge of the road bed); all others hibernated in relatively open woods dominated by Longleaf Pine (*Pinus palustris*), Wiregrass (*Aristida stricta*), and scrub oaks (*Quercus* spp.). Dates of hibernaculum entry ranged between 26 October and 24 November, and dates of first emergence ranged between 24 March and 10 April.

Two females were excavated from their hibernacula for recapture to remove or replace failed transmitters. Both were found in damp, firmly packed sand in narrow tunnels, apparently of their own making. One entered her hibernaculum between 26 and 31 October and was excavated on 29 November at a depth of ca. 26 cm (ca. 23 cm of sand and ca. 3 cm of surface litter). The other entered her hibernaculum between 28 October and 4 November and was excavated on 16 February at a depth of ca. 38 cm (ca. 36 cm of sand and ca. 2 cm of surface litter). Both were active when uncovered. The female that was tracked through two winters did not exhibit hibernaculum fidelity, but spent the second winter ca. 306 m from the hibernaculum she occupied the previous winter.

These observations suggest that *H. simus* do not depend on stump holes or other existing subterranean chambers for hibernacula (though they were sometimes observed using such sites when not hibernating). Other relatively large-bodied snake species that we have observed overwintering in the same area (several instances each for *Coluber constrictor*, *Elaphe guttata*, *Heterodon platirhinos*, *Masticophis flagellum*, *Pituophis melanoleucus*, *Agkistrodon piscivorus*, and *Sistrurus miliarius*) in all cases used existing stump holes, old root channels, or mammal burrows as hibernacula. Hibernaculum fidelity was observed on several occasions in *M. flagellum* and *P. melanoleucus*.

HYPSIGLENA OCHRORHYNCHA CHLOROPHAEA (Dusky-green Nightsnake). **DIET.** Previous records of the diet of nightsnakes have identified snakes and lizards, including eggs, as their primary prey items (Diller and Wallace 1986. Southwest. Nat. 31:55–64; Rodríguez-Robles et al. 1999. Copeia 1999:93–100; Setser and Goode 2004: Herpetol. Rev. 35:177). Here we provide observations on the diet of *H. ochrorhyncha chlorophaea* from Sonora and Coahuila collected as part of a survey of the herpetofauna of the Chihuahuan Desert and surrounding regions (Lemos-Espinal et al. 2004. Bull. Chicago Herpetol. Soc. 39:206–213; Smith et al. 2005. Bull Chicago Herpetol. Soc. 40:66–70). We examined the gut contents of 18 specimens collected in the

summers of 2003 and 2004 in Chihuahua, Sonora, and Coahuila. Of the 18 specimens, 12 had empty stomachs, 4 had unidentifiable contents, and 2 had identifiable prey items. One snake (SVL = 26.0 cm) from Cumpas, Sonora (30°2'5.8"N, 109°47'0.4"W, datum: WGS84; elev. 814 m) contained > 20 ants. A second snake (SVL = 16.0 cm) collected 53 km S Químicas del Rey (26°38'44.5"N, 103°9'13.4"W; datum: WGS84; elev. 1084 m) contained an orthopteran (length = 1.27 cm, width = 0.32 cm). Rodríguez-Robles et al. (1999. Copeia 1999:93–100) suggested that insects are rarely taken by small nightsnakes, but not by larger nightsnakes. Our observations confirm the presence of insects in the diets of *Hypsiglena*, particularly in smaller individuals.

HYPSIGLENA TORQUATA CHLOROPHAEA (Sonoran Nightsnake). **PREDATION.** Web-building spiders generally take prey their own size and larger (McCormick and Polis 1982. Biol. Rev. 57:29–58), including small snakes that become entangled in spider webs and are subsequently killed and consumed by the spider (Burt 1949. Herpetologica 5:127; Bayliss 2001. Herpetol. Rev. 32:48–49; Lazcano et al. 2005. Herpetol. Rev. 36:186; McKeown 1963. Australian Spiders. Angus and Robertson, Sydney. 287 pp.; Pinkus 1932. Sci. Mon. 34:80–83). Also, Zippel and Kirkland (1998. Herpetol. Rev. 29:46) reported finding a dead adult *Opheodrys aestivus* wrapped in silk in the web of a *Nephila clavipes*. Finally, an anecdotal report by Anderson (1930. Nat. Mag. Smithson. 16:234) describes the sequence of events of a "small green snake" falling into the web of an orb-web spider and becoming entangled; the spider periodically resecured and bit the struggling snake, and fed on it some three hours later after it ceased moving.

We report an additional observation of snake entrapment in a spider web from Chino Valley, Yavapai County, Arizona, USA (34.850833°N, 112.439739°W; 1345 m elev., WGS 84). On 15 August 2005, we found a dead adult *Hypsiglena torquata chlorophaea* (295 mm TL) suspended in the web of a black widow spider (*Latrodectus mactans*; Theridiidae), 0.5 m from the floor in a screened back porch. The spider was still attached to the snake. Both snake and spider are deposited in the herpetological collection of the California Academy of Science (CAS 233784). It is uncertain if this encounter represents an act of predation (the killing and consumption of prey). However, based on other reported predatory encounters between *L. mactans* and snakes, it is possible that the *H. torquata* did fall prey to *L. mactans.* Neill (1948. Herpetologica 4:158) reported independent predatory encounters between *L. mactans* and the snakes *Storeria dekayi* and *Opheodrys vernalis*.

MASTICOPHIS ANTHONYI (Clarion Racer). **DIET.** Snakes of the genus *Masticophis* have a varied diet (Camper and Dixon 2000. Texas J. Sci. 52:83–92), including taking chicks (e.g., Powell and Steidl 2000. Condor 102:823–831). *Masticophis anthonyi* is endemic to Clarion Island, Pacific Ocean, and is the only snake recorded from the Revillagigedo Archipelago (Slevin 1926. Proc. California Acad. Sci. 4th ser. 15:195–207). Virtually nothing is known about its diet (Brattstrom 1955. Amer. Midl. Nat. 54:219–229). During a study on breeding success of Laysan Albatrosses (*Phoebastria immutabilis*) on Clarion during 2002–2003, we discovered a *M. anthonyi* preying on a hatching albatross chick. Our presence disturbed the snake, which left the moribund chick uneaten. The albatrosses on Clarion experienced zero breeding success (0 fledglings of 46 eggs laid) in that season, and we speculate that predation by the snake was responsible for more failures than the single event we observed. Although this is the first record of seabird chick predation from this species, Slevin (1926, *op. cit.*) noted that it seemed most abundant around seabird colonies, suggesting an evolutionary history of seabird nest depredation by this species.

NERODIA RHOMBIFER (Diamond-backed Watersnake). **COURTSHIP AND DIET**. Gibbons and Dorcas (2004. North American Watersnakes: A Natural History. University of Oklahoma Press, Norman, Oklahoma. 438 pp.) report that there have been few observations of courtship behavior among watersnakes. Aggregate mating behavior has been reported for a few species of *Nerodia*, *Regina*, and *Seminatrix*, but it is not clear whether this behavior is prevalent in these species. For example, there is only a single observation of a probable mating aggregate involving three or four males and one female *Nerodia rhombifer* from Franklin County, Kansas (Gloyd 1928. Trans. Kansas Acad. Sci. 31:115–141), but at least three reported copulating pairs, one each from Kansas, Oklahoma, and Kentucky (Keck 2004. *In* Gibbons and Dorcas [eds.], North American Watersnakes: A Natural History, pp. 138–177. University of Oklahoma Press, Norman).

Herein, we describe mating behavior involving one female and three male *N. rhombifer*. At approximately 1330 h CST on 6 April 2006 at Estero Llano Grande State Park, Weslaco, Hidalgo County, Texas (26.126°N, 97.952°W, 18 m elev., WGS84), a large, female *N. rhombifer* corralled a relatively large Blue Tilapia (Perciformes: Cichlidae: *Oreochromis aureus*) and forced it up onto the shoreline of Alligator Lake, a small sheltered pond surrounded by a fragment of mesquite/spiny hackberry woodland. As the snake began to ingest the fish, at least three smaller conspecifics (presumed to be males) emerged from the water and approached the female. The larger female prevented at least one of the individual's

advances by incidentally hitting it with the fish. The three smaller individuals appeared to be attempting to effect cloacal apposition with the female. Eventually, the female moved off into the water with the fish still in her mouth and the smaller individuals struggling for position.

Our observations are similar to behaviors described by Mushinsky (1979. J. Herpetol. 13:127–129) for a mating aggregate of *Nerodia sipedon* in both orientation of the snakes relative to each other and the posture of the males on the female. The males were parallel to the female with their chins pressing on the female's dorsum, and the posterior portions of their bodies were coiled around the female. We could not determine whether the group moved to water because they were disturbed by the observer or because the female was attempting to escape persistent attempts at mating. It is also unclear whether copulation occurred.

This account documents a second occurrence of mating aggregations in *N. rhombifer* and is the only known case where the behavior occurred while a female was feeding. One factor that may affect the prevalence of multi-male courtship behavior in populations of *Nerodia* is the distribution of receptive females, which may be related to available substrate for mating (Brown and Weatherhead 1999. Behav. Ecol. Sociobiol. 47:9–16). Blue tilapia is a novel food item for *N. rhombifer*. The relative size of the tilapia is consistent with descriptions of ontogenetic shifts to larger prey sizes for diamond-backed watersnakes (Keck *op. cit.*).

We thank R. J. Edwards, F. W. Judd, and F. Zaidan for assistance.

Submitted by **RUBEN D. ZAMORA*** and **PETER VALADEZ**, Texas Parks and Wildlife, Estero Llano Grande State Park, 154A Lakeview Drive, Weslaco, Texas 78596, USA. *Current address: Edinburg North High School, 3101 North Closner Boulevard, Texas 78541, USA.

PITUOPHIS MELANOLEUCUS MELANOLEUCUS (Northern Pine Snake). **REPRODUCTION.** Female *Pituophis melanoleucus* are known to excavate their own nest chambers, at least in portions of their range (Moore 1893. Amer. Nat. 27:878–885; Zappalorti et al. 1983. Bull. Chicago Herpetol. Soc. 18:57–72.). Burger and Zappalorti (1986. Copeia 1986:116–121; 1991. J. Herpetol. 25:152–160) reported extensively on nesting behavior of *P. m. melanoleucus* in the New Jersey Pine Barrens. However, information on nesting in other portions of the range of *P. melanoleucus* is scant. We here describe a natural nest from the Sandhills region of North Carolina.

On 22 September 2006, a nest was located after LTP discovered a live hatchling and a road-killed hatchling female (433 mm SVL, 60 mm tail length) *P. m. melanoleucus* within a few m of each other on a paved road (4.5 km S.SE Eagle Springs, Moore County, North Carolina, USA). After a search of <1 h, the nest was found in an open area along a fence line at the edge of a horse pasture, 14.8 m from the edge of the paved road. The nest was not readily obvious, as the small "apron" or "dump pile" of sand around the nest entrance had been obscured by weather and dead leaves. Shed skins, or fragments thereof, from at least eight hatchlings were found either inside the nest tunnel or outside it <1 m from the entrance. A large female Southern Black Widow spider (*Latrodectus mactans*) had constructed a web in the nest entrance. We excavated the nest and found it contained nine adherent, recently hatched eggshells. The nest tunnel was 69 cm in total length—shorter than any among 22 New Jersey nests reported by Burger and Zappalorti (1986, *op. cit.*), and well below the mean (140 ± 7 cm), but within the range (39–228 cm), reported by Burger and Zappalorti (1991, *op. cit.*) in a study of 93 nests in New Jersey. The bottom of the nest chamber was 41 cm below the surface. Interestingly, of 93 nest chambers described by Burger and Zappalorti (1991, *op. cit.*), none was deeper than 25 cm. The road-killed hatchling (presumably, but not conclusively, from this nest) and eggshells are deposited in the collection of the North Carolina State Museum of Natural Sciences (NCSM 71769 and 71770, respectively). The live hatchling was released.

To our knowledge, this is the first published description of a natural nest of *P. m. melanoleucus* outside of the New Jersey Pine Barrens. We thank Wayne, Angela, and Chance Greene for permitting access to their private land.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Research Laboratory, 4301 Reedy Creek Road, Raleigh, North Carolina 27607, USA (e-mail: jeff.beane@ncmail.net); and **L. TODD PUSSER**, P.O. Box 122, West End, North Carolina 27376, USA (e-mail: tpusser@nc.rr.com).

REGINA RIGIDA (Glossy Crayfish Snake). **MELANISM**. On 11 April 2004, while conducting a herpetological survey of Cat Island (Tom Yawkey Wildlife Center, Georgetown County, South Carolina), we captured a completely melanistic specimen of *Regina rigida* (198 mm SVL, 56 mm tail length) as it crossed a sand road at dusk. The specimen was uniformly black on both dorsum and venter. Melanism has been reported previously in this species (Etheridge 1950. Copeia 1950:321; Shoop 1959. Herpetologica 15:160), but only for the southeastern portion of Louisiana and from the area near the mouth of the St. Johns River in Florida and not in more than 45 years. The specimen was released at the point of capture. During the course of the survey two additional *Regina rigida* were collected that both exhibited typical coloration. Photographic vouchers of the specimen are deposited in the South Carolina State Museum (2005.82.1–8).

Submitted by **WILL DILLMAN** and **TIMOTHY MOUSSEAU**, Department of Biological Science, University of South Carolina, Columbia, South Carolina 29208, USA.

THAMNOPHIS CYRTOPSIS COLLARIS (Black-necked Gartersnake). **DIET AND BROOD SIZE.** The natural history of *Thamnophis cyrtopsis* in Mexico is relatively unknown. Here we provide observations on the diet and brood size of *T. cyrtopsis* collected as part of a survey of the herpetofauna of the Chihuahuan Desert (Lemos-Espinal et al. 2004. Introducción a los Anfibios y Reptiles del Estado de Chihuahua, CONABIO. 128 pp.). We examined the gut contents and reproductive tracts of 9 specimens of *T. cyrtopsis* collected in the summer 2003 near Chínipas, Chihuahua (27°23'29.9"N, 108°32'9.7"W, datum: WGS84; elev. 469 m) (see Lemos-Espinal et al. 2004. Bull. Chicago Herpetol. Soc. 39:206–213). Of the 9 specimens, 8 had empty stomachs. The

single specimen that contained a prey item was a juvenile of unknown sex (SVL: 16.5 cm). The single prey item was a toad (*Bufo* sp.) metamorph. This observation of a toad metamorph in the diet of *T. cyrtopsis* is consistent with the few other observations of the diet in other parts of their range. Previous studies on the diet of *T. cyrtopsis* suggest the diet of this species consists primarily of frogs and other aquatic organisms (e.g., fish, tadpoles, etc.) (Fleharty 1967. Southwest. Nat. 12:207–229; Smith et al. 2005: Herpetol. Rev. 36:300). Indeed, Jones (1990. Southwest. Nat. 35:115–122) found *T. cyrtopsis* spends much of its time foraging in the water, but also noted it appears to be a generalist forager. One of the females (34.0 cm SVL) we examined contained 9 ovarian follicles. The only other previous report of brood size in *T. cyrtopsis* from Mexico (San Luis Potosí) also reported a brood size of 9 for a female with an SVL of 54.2 cm) (Ramírez-Bautista et al. 2000. Herpetol. Rev. 31:180).

SMITH**, Department of Ecology and Environmental Biology, University of Colorado, Boulder, Colorado 80309, USA (e-mail: hsmith@colorado.edu).

THAMNOPHIS ORDINOIDES (Northwestern Garter Snake)**. EXOTIC PREY.** *Thamnophis ordinoides*, a garter snake endemic to the moist coastal regions of Pacific North America (Stebbins 2003. Field Guide to Western Reptiles and Amphibians. Houghton Mifflin, New York. 519 pp.), consumes a large proportion of molluscs and annelid worms (Fitch 1941. California Fish Game 27:2–32; Fox 1952. Herpetologica 8:4–8; Gregory 1978. Can. J. Zool. 56:1967–1974). However, the exact species of such prey have not been reported. Here, I provide four observations of predation by *T. ordinoides* on an introduced annelid, the African nightcrawler (*Eudrilus eugeniae*).

Three observations were made ca. 1.6 km W of Aurora, Marion County, Oregon, USA (UTM 5008761N, 516528E, WGS84). On 24 July 2004, at 1850 h, CJR captured a juvenile male *Thamnophis ordinoides* (201 mm SVL, 55 mm tail, 3 g) with a markedly distended abdomen. The snake was resting beneath a piece of corrugated aluminum on dry grass and soil (air temperature = 21.8°C). Palpation of the snake revealed its prey to be a mature African nightcrawler, *Eudrilus eugeniae*. The anterior end of the worm had been swallowed first, and was partly digested. The remains of the worm were 182 mm long, 6.2 mm wide, and 1.72 g (the worm was dried with a paper towel to remove excess water and saliva prior to weighing). After measuring, the snake was photographed and released.

On 5 April 2004, at 1800 h, CJR observed another male *T. ordinoides* (ca. 260 mm SVL) capturing an adult *E. eugeniae* (beneath a piece of aluminum, on soil and dry grass, ca. 20 m east of the previous snake). When discovered, this snake had the anterior end of the worm in its jaws and was attempting to pull the worm from its burrow; loops of the snake's body were braced against the grass for leverage. At this point, the snake had extracted and swallowed the anterior 40 mm of the worm; upon capture, it released the worm, which bore lacerations on the anterior 5mm of its body from the snake's teeth. The snake was replaced under the aluminum; 5 min later, the snake had recaptured the worm and reswallowed the anterior 40 mm. A final observation, made 10 min after the initial encounter, revealed the snake to have completely extracted and consumed the worm; the snake was resting in a coiled position on the dry grass (under the aluminum).

On 06 August 2006, JAR collected a juvenile *T. ordinoides* (135 mm SVL, 10 mm tail [broken], 1.21 g) ca. 50 m west of the previous two snakes. The snake, dead when found, appeared to have been run over. It had recently swallowed an adult *E. eugeniae*, 7 mm of which was protruding from its mouth. The worm (131 mm, 1.19 g) was missing its posterior end, and had been swallowed anterior end first.

Evidence that *E. eugeniae* may be more than an occasional prey for *T. ordinoides* is provided by a final observation. At 1820 h on 02 June 2006 CJR captured an adult female *T. ordinoides* (520 mm SVL, 130 mm tail, 100 g) crawling across a piece of corrugated aluminum at the edge of a gravel road at the Little White Salmon National Fish Hatchery, Skamania County, Washington, USA (45.773056°N, 121.781667°E**,** WGS 84). Upon capture, this snake regurgitated the remains of at least five adult *E. eugeniae*, including two whole worms measuring 166 mm and 180 mm, respectively. The total mass of regurgitated worms was 8.6 g. Worm remains ranged from very fresh to heavily digested.

E. eugeniae is not native to the United States and has been introduced primarily for fish bait but is now established in portions of western Oregon and Washington (C. Rombough, pers. obs.). It is a large (to > 200 mm) anecic worm with a setae-lined, spoon-shaped tail, which it uses to resist being pulled from its burrow, making it a seemingly difficult prey to obtain. Of special note is the fact that in two of the cases reported here (24 July 2004 and 06 August 2006), the worms were almost as long as the snakes which ate them, and potentially greater in mass. Though these observations demonstrate the ability of *T. ordinoides* to prey on *E. eugeniae*, further data are needed to determine the effect of such predation on *T. ordinoides* populations.

Submitted by **CHRISTOPHER J. ROMBOUGH** (e-mail: rambo2718@yahoo.com) and **JEFFREY A. ROMBOUGH**, P.O. Box 365, Aurora, Oregon 97002-0365, USA (e-mail: bigjfire@yahoo.com).

UROTHECA* (*PLIOCERCUS*) *EURYZONUS (Halloween Snake). **DIET**. *Urotheca euryzonus* occurs from northern Nicaragua to western Ecuador and feeds on salamanders and adult frogs (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. The University of Chicago Press, Chicago, Illinois. 934 pp.).

On 24 June 2004, we observed an *U. euryzonus* feeding on *Agalychnis callidryas* (Red-eyed Treefrog) eggs inside a small pool formed within the rusting back end of a tractor abandoned along the road from El Copé to La Rica, 100 m N of the visitor's center of Parque Nacional General de División Omar Torrijos Herrera, El Copé, Panamá (8°40'5.15"N, 80°35'33.41"E; 708 m elev.).

Agalychnis callidryas eggs typically are laid on leaves overhanging water, but on 22 June 2004 we found 20–30 *A. callidryas* tadpoles and more than 50 *Smilisca phaeota* tadpoles inside the tractor pool. On the evening of 23 June 2004, we captured (and subsequently released) two *A. callidryas* males near the tractor and heard a third calling. Also, we observed a *S. phaeota* male calling from within the tractor pool. Mid-morning on 24 June 2004 we checked the tractor and observed a new *A. callidryas* egg clutch, resting on the flat metal ledge above the water inside the tractor pool, and a new *S. phaeota* clutch, in the water. We did not count the number of eggs in the clutch, but *A. callidryas* clutches average 40–68 eggs (Pyburn 1963. Texas J. Sci. 14:155–170). When we arrived at the tractor at 2000 h on 24 June, an *U. euryzonus* was already consuming *A. callidryas* eggs, and there were fewer than ten eggs left. The *S. phaeota* eggs were untouched. From 2001 h until 2004 h the snake consumed the remaining eggs. The snake opened its mouth wide and descended on the eggs from above, scooping eggs and jelly into its mouth (Fig. 1). During feeding, the snake paused after consuming each egg, looked around, and sometimes retreated from the egg mass for several seconds. Our headlamps and the flash from the camera might have interrupted feeding. After eating the last egg, the snake traversed the edge of the water, darting its head erratically, flicking its tongue, moving in quick stops and starts, and often shooting forward and then retreating. By 2006 h the snake left the tractor, and moved into the surrounding vegetation.

In the most recent published phylogeny, *Urotheca* is placed within one of five clades of the Dipsadinae along with *Coniophanes*, *Rhadinaea*, and *Trimetopon*. Both *Coniophanes* and *Rhadinaea* feed on the terrestrial eggs of *Eleutherodactylus* frogs (Savage 2002, *op. cit.*, pp. 594–627), but species of *Urotheca* or *Trimetopon* have not been reported to eat frog eggs. Snake predators of frog eggs occur in two other clades of dipsadines, including *Imantodes inornatus* and *Leptodeira septentrionalis* in the Dipsadini (Donnelly and Guyer 1994. Oecologia 98:291–302), and *Sibon argus* in the 'goo-eater' clade (Ryan and Lips 2004. Herpetol. Rev. 35:278). Our report of *U. euryzonus* eating frog eggs thus suggests promising avenues for future work on the evolution of diet and feeding ecology in dipsadine snakes.

FIG. 1. *Urotheca* (*Pliocercus*) *euryzonus* consuming *Agalychnis callidryas* eggs in a tractor abandoned on the edge of a Panamanian montane forest.

We thank H. W. Greene for encouraging us to submit this note, and for comments on an earlier draft. Financial support provided by the Mellon Foundation and am Organization for Tropical Studies grant to JMR.

WAGLEROPHIS MERREMII (Boipeva). **REPRODUCTION.** *Waglerophis merremii* is a ground-dwelling, diurnal snake found throughout much of South America. Reported clutch sizes are 6–8 eggs (Amaral 1977. Serpentes do Brasil. Melhoramentos, SP, 248 pp.), 5–29 eggs (Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras. Ciências, RJ, 161 pp.), and 7–35 eggs (Pontes and Di-Bernardo 1988. Comum. Mus. Ciênc. PUCRGS, Ser.Zool. 1:123–149).

On 11 May 2000, I found 71 *W. merremii* eggs inside a termite nest on Santa Elisa Farm (22°36'S, 46°14'W, 1650 m elev.), in the municipality of Munhoz (Minas Gerais, Brazil). I also found a carangejeira spider (*Vitalius* sp.) and pieces of a lizard's (*Tupinanbis* sp.) shed skin. The eggs were at a depth of 60 cm and organized in the following manner: 33 eggs were isolated and the remainder occurred in groups of 18, 10, 6, and 4 eggs. Fifty-five eggs had already hatched, 14 eggs were close to hatching, and two were unfertilized. The fourteen healthy eggs (ranging from 8.3–8.5 g, 30–36 mm long, 20–24 mm wide) were incubated in the laboratory and all hatched between 8–18 days after collection, resulting in nine male (range = 160–185 mm SVL, 25–35 mm TL, 5.3–7.2 g) and five female (range = 170–190 mm SVL, 25–30 mm TL, 6.2–7.3 g) neonates.

Although it was not possible to determine whether or not this is a communal nest, the large number of eggs, together with the configuration of the nest site are suggestive of communal use. There are few reports of communal nesting by South American snakes, although these are usually associated with species that inhabit cold areas. Albuquerque and Ferrarezi (2004. Phyllomedusa 3:73–77) report a *Sybinomorphus mikanii* nest with 66 eggs that were not stuck together and contained embryos in different stages of development (more suggestive of communal nesting). The present observation is either a novel report of communal nesting or a new upper limit on litter size in this species.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 37, Number 1 (March 2006). Please note that the responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extension reports unless a thorough literature review has been completed.

CAUDATA

EURYCEA LONGICAUDA MELANOPLEUARA (Dark-Sided Salamander). USA: ARKANSAS: JOHNSON CO.: (35°41'21"N, 93°36'27"W elev. 308 m). 19 September 2006. Glenn J. Manning. University of Kansas Natural History Museum (KU CT 12010–12012). Verified by John E. Simmons. This individual was found under a rock near a small wet drainage within the Ozark National Forest. First county record (Trauth et al. 2004 The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

Submitted by, **GLENN J. MANNING**, Department of Biology, University of Arkansas, 601 SCEN, Fayetteville, Arkansas 72701, USA; e-mail: gmannin@uark.edu.

EURYCEA LUCIFUGA (Cave Salamander). USA: ARKANSAS: JOHNSON CO.: 35°41.478'N, 93°36.565' W; elev. 344 m. 14 October 2006. Glenn J. Manning and Kory Roberts. University of Kansas Natural History Museum (KU 307072). Verified by John E. Simmons. Ths specimen was collected during the fall 2006 field trip of the Arkansas Herpetological Society. This specimen was found in a small muddy cavity in a rocky drainage within the Ozark National Forest. First county record (Trauth et al. 2004 The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

Submitted by, **GLENN J. MANNING**, Department of Biology, University of Arkansas, 601 SCEN, Fayetteville, Arkansas 72701, USA (e-mail: gmannin@uark.edu); and **KORY ROBERTS**, 8 Castle Acre Lane, Bella Vista, Arkansas 72714, USA (e-mail: webmaster@snakesofarkansas.com).

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: WISCONSIN: IRON CO.: Duck Lake Road, 3.1 km W junction of Duck Lake Road and Chippewa Fire Lane (46°10.933'N; 90°24.101'W; 512 m elev.: T43N R1E NW1/4 Sec 29). 05 May 2006. E. R. Wild. University of Wisconsin-Stevens Point, Natural History Museum, Herpetology Collection (UWSP 3745–46, UWSP 3747–48). Verified by Rori A. Paloski. New county record completing documentation of distribution along Wisconsin-Lake Superior shoreline and western Wisconsin-upper peninsula of Michigan border. (Casper 1996. Geographic Distributions of the Amphibians and Reptiles of Wisconsin. An Interim Report of the Wisconsin Herpetological Atlas Project, Milwaukee Public Museum. 87 pp.).

Submitted by **NATHAN HAISLIP**, 3817 Mooresville Highway, Culleoka, Tennessee 38451, USA; e-mail: nhaislip@utk.edu.

BUFO MARINUS (Marine Toad). USA: FLORIDA: BAY CO.: Florida Hwy 77, ca. 10 km N of junction County Road 2302 (30°21'56.7"N, 85°40'08.7"W). 17 June 2007. Jason Dombrowsky. Four subadults collected on grounds of abandoned Panama City Zoo. FLMNH 151348–151351. Verified by Kevin Enge. First record from the Florida panhandle, extending range ca. 500 km by land from nearest records in Citrus (Stevenson and Crowe 1992. Herpetol. Rev. 23:85) and Pasco counties (Meshaka et al. 2004. Exotic Amphibians and Reptiles of Florida. Krieger Publishing Company, Malabar, Florida. 155 pp.).

Toads found among two former pond exhibits that had become partially overgrown with wetland vegetation. The former zoo owner released six adult *Bufo marinus* at the site five years ago, and Marine Toads have been regularly observed at the site for two years. Several hundred larvae observed on 20 June 2007 and a single calling male heard on 02 August 2007 by JGH indicate that this is a reproducing population. It is not currently known whether the toads are still restricted to the immediate vicinity of the abandoned zoo.

Previously known from subtropical Atlantic rainforest and parts of the Araucaria forest in southern Brazil (states of Rio Grande do Sul and Santa Catarina) and Misiones, Argentina (Kwet and Solé 2005. J. Herpetol. 39:521–532; Frost 2007. Amphibian Species of the World: An Online Reference: V5.0 http://reserarch.amnh.org/herpetology/amphibia/index./html). This new record extends known distribution ca. 161 km NW from Caxias do Sul, State of Rio Grande do Sul, Brazil (Kwet and Solé, *op. cit.*).

Submitted by **NOELI ZANELLA** (e-mail: zanella@upf.br), **CARMEN SILVIA BUSIN,** and **LEONARDO CRESTANI**, Universidade de Passo Fundo, Campus I, Bairro São José, Br 285, Km 171, Caixa Postal 611, CEP 99001-970, Passo Fundo, Rio Grande do Sul, Brazil.

ELEUTHERODACTYLUS PLANIROSTRIS (Greenhouse Frog). USA: LOUISIANA: St. Tammany Parish: Mandeville (30°22'5"N, 90°3'37"W). 04 August 2006. Jean Elbers. Verified by Brian Crother. Deposited in Museum of Natural History, Tulane University (TU 24205, one adult). New parish record that extends the distribution north across Lake Pontchartrain. This species originates from Cuba and other Caribbean Islands (Goin 1947. Studies on the Life History of *E. r. planirostris* (Cope) in Florida. Univ. Florida Studies, 66 pp.). It has been known in Florida as of 1875 and may have been introduced by shipments of foreign Caribbean plants (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge. 300 pp.). In Louisiana, this species has been documented in Orleans Parish as early as 1975 (Plotkin and Atkinson 1979. Herpetol. Rev. 10:59) and has spread to Easton Baton Rouge, Calcasieu, St. Bernard and St. John the Baptist, and Plaquemines Parishes (Boundy 1998. Herpetol. Rev. 29:251–252; Boundy 2004. Herpetol. Rev. 35:194–196; Platt and Fontenot 1995. Herpetol. Rev. 26:207; Williams and Wygoda 1997. Herptol. Rev. 28:207). This species may compete with native *Gastrophryne carolinensis* (Eastern Narrow-mouthed Toad) (Dundee and Rossman 1989, *op. cit.*; Goin 1947, *op. cit*.). In Louisiana, the two species have been found sympatrically (pers. obser.).

I thank B. Crother, C. Fontenot, and T. Schriever for specimen identification and manuscript comments.

GASTROPHRYNE OLIVACEA (Great Plains Narrow-mouthed Toad). USA: TEXAS: Van Zandt Co.: Pasture along Van Zandt County Road 2721, 2.90 km N of jct. with US 198. 24 May 2007. R. Michael Burger. Verified by Carl J. Franklin. Color photo voucher. University of Texas at Arlington - Amphibian and Reptile Diversity Research Center (UTA color images 1046–1047). Adult male 25 mm SVL located by vocalization after heavy rain. Several other calling males were in the immediate vicinity. New county record (Dixon 2000. Amphibians and Reptiles of Texas. 2nd ed. Univ. of Texas A&M Press, viii+421 pp.).

Submitted by **R. MICHAEL BURGER**, P.O. Box 4099, Dallas, Texas 75208, USA; e-mail: mvburger@dctexas.net.

GASTROTHECA DENDRONASTES (Río Calima Marsupial Frog). COLOMBIA: DEPARTAMENTO DE ANTIOQUIA: Municipio Anorí, Finca El Chaquiral, Vereda El Retiro (06°59'0.4"N, 75°07'59"W, ca. 1704 m elev.), northern part of Cordillera Central. 18 November 2004. J. C. Arredondo-S. and C. Molina-Z. Museo de Herpetología Universidad de Antioquia, Medellín, Colombia (MHUA 3868, female). Verified by J. D. Lynch. Previously known only from the Río Calima, 1.5 km (by road) W of Lago Calima (1230 m elev.), Departamento del Valle del Cauca, Cordillera Occidental, Colombia and Río Faisanes, 14

km ENE of Las Palmas (1380 m elev.) Provincia de Pichincha, Ecuador (Duellman 1983. Copeia 1983:868–874). This record extends the known distribution ca. 374 km from its nearest known locality, toward the northeastern part of Colombia through the eastern versant of the Cordillera Central. First documented record from Departamento de Antioquia and from the Cordillera Central. Ruiz et al. 1996 (Rev. Acad. Colomb. Cienc. 20:365–415) and Acosta-Galvis 2000 (Biota Colombiana 1:289–319) mentioned that this species is present at Departamento de Antioquia, but no voucher exists to support their assertions.

Submitted by **PAUL D. A. GUTIERREZ-C.** and **LUCAS S. BARRIENTOS**, Grupo Herpetológico de Antioquia (GHA), Instituto de Biología, Universidad de Antioquia, oficina 7-121, teléfono 574-2105628, A.A. 1226, Medellín, Colombia (e-mail: pdgutierrez2@yahoo.com).

HYALINOBATRACHIUM EURYGNATHUM (Rio Glass Frog). BRAZIL: BAHIA: Municipality of Amargosa, Timbó farm (13°07'21"S, 39°39'4051"W) 750 m elev. 15 January 2007. P. Fonseca. Museu de Zoologia da Universidade Federal da Bahia, Salvador, Brazil (MZUFBA 6491; 6505). Collected at night on the ground of the forest. Verified by M. Napoli. Previously known from highlands of southeastern Brazil in Rio de Janeiro, Espírito Santo, and south Bahia state (Frost 2007. Amphibian Species of the World, An Online Reference, ver. 5.0; Freitas et al. 2004. Herpetol. Rev. 35:281). First record from northern Bahia, Brazil; extends distribution ca. 310 km N from Itapebi municipality, Bahia (Freitas et al., *op. cit.*).

Submitted by **MARCO ANTÔNIO DE FREITAS,** Programa de pós-graduação em zoologia, UESC (Universidade Estadual de Santa Cruz) CEP 46.500-000 Rodovia Ilhéus/Itabuna, Ilhéus, Bahia, Brazil (e-mail: philodryas@hotmail.com); and **THAÍS FIGUEIREDO SANTOS SILVA,** Biogeographia publicações e consultoria ambiental, Rua E quadra D lote 11, Jardim Aeroporto, CEP 42700-000, Lauro de Freitas, Bahia, Brazil; and **PATRÍCIA FONSECA** (e-mail: patriciamfonseca@yahoo.com.br), Instituto de Biologia, Museu de Zoologia da Universidade Federal da Bahia (UFBA) CEP 40000-000, Salvador, Bahia, Brazil.

HYLA CHRYSOSCELIS/VERSICOLOR (Gray Treefrog). USA: ILLINOIS: Putnam Co.: Highway 26, 5.5 km N of Highway 18 (41°08.966'N, 89°18.249'W). 26 May 2007. John G. Palis. Verified by Jeffrey G. Stewart. Southern Illinois University at Carbondale (SIUC H-8678). DOR adult at 2145 h. *Hyla versicolor* heard vocalizing from several locations along Highway 26. First record for county, filling gap among Bureau, LaSalle, and Marshall counties (Petzing et al. 2000. Herpetol. Rev. 31:189–194; Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois xii + 282 pp.).

GRAPTEMYS ERNSTI (Escambia Map Turtle).USA: FLORIDA: Holmes Co.: Pea River, 0.15 mi S SR 2 (30°56'51.2"N, 85°50'35.4"W, WGS84, elev. 20.4 m). 01 September 2007. Christopher J. Lechowicz and John Archer. Verified by Kenneth L. Krysko. Florida Museum of Natural History (photographic voucher UF 151595). New county record and first record in the Choctawhatchee River drainage (Aresco and Shealy 2006. *In* P. A. Meylan [ed.], Biology and Conservation of Florida Turtles, pp. 273–278. Chelonian Research Monographs No. 3).

Submitted by **CHRISTOPHER J. LECHOWICZ,** Sanibel-Captiva Conservation Foundation, Sanibel, Florida 33957, USA (e-mail: clechowicz@sccf.org); and **JOHN ARCHER,** Medinah, Illinois 60157, USA (e-mail: j-archer@sbcglobal.net).

KINOSTERNON ARIZONENSE (Arizona Mud Turtle). USA: ARIZONA: Maricopa Co.: Sonoran Desert National Monument, Vekol Valley (32°39'45"N, 112°12'42"W) 619 m elev. 16 August

2006. Thomas R. Jones, Bruce D. Taubert, Mark L. Zornes, and Randall D. Babb. Verified by George Bradley. University of Arizona Museum (photo voucher by R. D. Babb; UAZ 56581-PSV). An adult male was found on the berm of a spreader dike that seasonally impounds flood waters (Branson 1956. J. Range Mgmt. 9:187–191). Limited attempts to trap additional individuals were unsuccessful. This is the northernmost record (new county record) and the only verified record for the Gila River drainage.

Iverson (1989. Southwest. Nat. 34:356–368) concluded that in the Arizona portion of its range *K.* [*flavescens*] *arizonense* was confined to two river basins, the Río Sonoyta and Río de la Concepción, which empty into the Gulf of California in NW Sonora, México. Although Iverson (*op. cit.*) mentioned an unconfirmed sighting in the Gila River drainage, none has been verified. One credible sight record from 1996 (Arizona Game and Fish Department Heritage Database Management System) is from the upper reaches of the Kaka Valley, Tohono O'odham Indian Reservation, 21 km SSW of the Vekol Valley site (Troy Corman, pers. comm.). The Kaka Valley drains into Kohatk Wash, and ultimately N into the Santa Cruz River, a Gila River tributary.

The southern end of Vekol Valley is separated from headwaters of the Kaka Valley and Kohatk Wash by a low elevation divide of less than a few meters, thus turtle movement into Vekol Valley from the south would not be unexpected.

We thank Cristina Jones, Lisa Bucci, Paul Moler, and Barry Mansell for assistance with trapping efforts.

MESOCLEMMYS VANDERHAEGEI (NCN). ARGENTINA: CORRIENTES: Departamento Santo Tomé: Garruchos (28°92'59"S, 55°43'15"W). 21 January 2007. E. Etchepare. Colección Herpetológica de la Universidad Nacional del Nordeste, Corrientes, Argentina (UNNEC 9077; juvenile carapace, length 63.9 mm; plastron length 55.4 mm; shell depth 24.5 mm). Verified by M. Cabrera. *M. vanderhaegei* is distributed in the basin of Paraguay River from Cuibá, Mato Grosso, Brazil, through eastern Paraguay to northeastern Argentina (Bour and Zaher 2005. Pap. Avul. Zool. 45:298–311; Cei 1993. Reptiles del Noroeste, Nordeste y Este de la Argentina. Museo Regionale di Scienze Naturali, Monografía XIV, 949 pp.; Cei 1998. Las Tortugas Continentales de Sudamérica Austral, 114 pp.). Previously known in Argentina from Misiones and Santa Fe provinces (Cabrera, *op. cit.*). First province record, fills the gap between Arroyo Zaimán, Misiones (90 km NW from Garruchos) and Malabrigo, Santa Fe (300 km SW from Garruchos).

Submitted by **EDUARDO GABRIEL ETCHEPARE,** Anatomía Comparada de los Cordados, Laboratorio de Herpetología, Departamento de Biología, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste. Av. Libertad 5470. CP 3400. Corrientes. Argentina; e-mail: eduardoetchepare@hotmail.com.

PSEUDEMYS TEXANA (Texas River Cooter). USA: TEXAS: Burnet Co.: Specimen was found about 3.2 km SW of the intersection of Ranch Road 2341 and County Road 114, at Val Montgomery's Revelle Park Ranch (30.78464°N, 98.35508°W, WGS84, 300 m elev.). 29 April 2007. Toby Hibbitts. Verified by Heather Prestridge. Texas Cooperative Wildlife Collection, TCWC 91808. First county record (Dixon 2000. Amphibians and Reptiles of Texas. 2nd Edition. Texas A&M Univ. Press, College Station, Texas, 421 pp.). Two other specimens were found on 15 March 2007: one intact shell (John H. Duvall-Jisha and James R. Dixon, TCWC 91852) and one decomposing entire specimen (Josie L. Duvall, TCWC 91853) were found about 1 km SSW of the intersection of US Highway 281 and Park Road 4, within an impounded tributary of Honey Creek, at the creek edge (30.68105°N, 98.26469°W, WGS84, 352 m elev.).

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). USA: ARKANSAS: Izard Co.: Found in a hayfield on private property off Co. Rd. 3, 4 km E of St. Hwy 9. UTM 15N 0597591E, 3987699N. 28 March 2007. Collected by M. B. Connior and I. Guenther. Arkansas State University Herpetological Museum (ASUMZ 30427). Caught by hand. Verified by Stanley E. Trauth. First county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. The University of Arkansas Press, Fayetteville, Arkansas. 421 pp.).

We thank K. Irwin and B. Sasse from the Arkansas Game and Fish Commission for support of our study, Y. and N. Whitehurst, M. and K. Smith, and R. and S. Smith for permission to conduct the study on their land, and S. Trauth for specimen verification and curatorial preparation. Thanks also to the ASU Wildlife Management Investigational Techniques class for installing the drift fences.

Submitted by **MATTHEW B. CONNIOR**, **IDUN GUENTHER**, and **THOMAS S. RISCH,** Department of Biological Sciences, Arkansas State University State University, Arkansas 72467, USA (e-mail: matthew.connior@smail.astate.edu).

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: FLORIDA: Palm Beach Co.: West Palm Beach, South Florida Water Management District Office, 3301 Gun Club Road (26°40'32"N, 80°05'40"W). 12 December 2006. Ellen M. Donlan. Hatchling collected by hand in a manmade pond while trying to enter a baited hoop trap. UF 150156. New county record (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publishing Co., Malabar, Florida, 155 pp.). Eleven adults were also trapped here in six hoop traps on 12–13 December 2006. At the same pond, an adult male Ouachita Map Turtle (*Graptemys ouachitensis ouachitensis*) was trapped on 13 December 2006. Kevin M. Enge. UF 150157. Verified by Christopher J. Lechowicz. New state record but no evidence of reproduction. *Trachemys scripta elegans* is an introduced species in southeastern Florida,

where it is common in many canals, rock pits, lakes, and ponds in urban and suburban areas. However, it has only been reported from two of the Florida Keys, Monroe Co. (Butterfield et al. 1994. Herpetol. Rev. 25:81; Krysko and Sheehy 2005. Carib. J. Sci. 41:169–172; Meshaka et al., *op. cit.*), several sites in Miami-Dade Co. (Meshaka et al., *op. cit.*), and in Davie, Broward Co. (Johnston and Johnston 2003. Herpetol. Rev. 34:164).

We documented additional sites in Miami-Dade and Broward counties. In Miami-Dade County we trapped 28 adults (UF 146977, 147508–9); three adults (UF 146973–5); four adults (photographic voucher UF 150241; five adults and one juvenile (photographic voucher UF 150242); and six adults (UF 137005–8). In Broward County we trapped six adults (UF 150243).

ANOLIS CAROLINENSIS (Green Anole). USA: TEXAS: Burnet Co.: 500 m E of Hwy 281 and 9.4 km N of Marble Falls (30°40.730'N, 98°15.834'W). 25 May 2007. Daniela Buzo, Michele A. Gaston, Julie A. Parlos, James R. Dixon, and Michael R. J. Forstner. Verified by Toby Hibbits. Texas Cooperative Wildlife Collection (TCWC 91817). SVL 54 mm, tail 100 mm. This female specimen represents the first recorded occurrence for the county.

Submitted by **[1]DANIELA BUZO** (e-mail: db1243@txstate.edu), **[1]MICHELE A. GASTON**, **[1]JULIE A. PARLOS**, **[2]JAMES R. DIXON**, and **[1]MICHAEL R. J. FORSTNER**, [1]Department of Biology, Texas State University, San Marcos Texas 78666, USA; [2]Texas Cooperative Wildlife Collection, Texas A&M University, College Station, Texas 77843,USA.

ANOLIS EQUESTRIS (Knight Anole). USA: FLORIDA: Brevard Co.: 4310 MacTavish Street, Cocoa (28°27'56.24"N, 81°47'27.00"W). 03 June 2007. Diane M. Coben. Two adults were observed mating in a tree in the backyard of a residence in the Port St. John area. Verified by Kenneth L. Krysko. Florida Museum of Natural History photo voucher (UF 150871). New county record. Extends range ca. 134 km N of the closest known locality in St. Lucie Co. (Krysko et al. 2005. Herpetol. Rev. 36:85–87). An individual was also observed here in 2006.

Submitted by **KEVIN M. ENGE**, Florida Fish and Wildlife Conservation Commission, 4005 South Main Street, Gainesville, Florida 32601, USA (e-mail: kevin.enge@myfwc.com); and **DIANE M. COBEN**, 4310 MacTavish Street, Cocoa, Florida 32927, USA; (e-mail: diane.coben@pwr.utc.com).

ANOLIS SAGREI (Brown Anole). USA: FLORIDA: Leon Co.:, Tallahassee, Tallahassee Nurseries, 2911 Thomasville Road (30.48316°N, 84.25693°W). 23 May 2007. Dale R. Jackson. Verified by Kenneth L. Krysko. Florida Museum of Natural History: adult male (UF 151203, 59 mm SVL) and three adult females (UF 151200–151202, 46–47 mm SVL); these were among nine individuals, including three adult males, observed during a 1-h search from 1200–1300 h EST. First vouchered records for county although past sightings of the species elsewhere in the vicinity have

been made (K. Enge, K. Krysko, pers. comm). I have not observed the species at this site in past years. All individuals observed were within a 45-m radius centered around a single shed and adjacent greenhouse on the 6-ha property, this suggests that the introduction was recent. I examined reproductive tracts of two of the females; one contained a single shelled egg, and the second a shelled and an unshelled egg. All three females bore small dewlaps colored as in males.

This is only the fourth documented record for the "Panhandle" (Means 1990. Herpetol. Rev. 21:96; Means 1996. Herpetol. Rev. 27:151–152; Townsend et al. 2002. Herpetol. Rev. 33:75; Meshaka 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publ. Co., Malabar, Florida. 155 pp.) and the most inland of these (43 km from coast), although several localities further north in Georgia have been recorded (J. Jensen, pers. comm.). The species' widespread distribution has been attributed in large part to incidental dispersal among ornamental plants via the nursery industry as well as to vehicular transport (Meshaka, *op. cit.*). Both of the occurrences reported by Means (*op. cit.*) from west of Leon Co. exhibited high winter mortality. However, the presence of buildings and greenhouses at the present site, coupled with gravid females, suggests the potential for long-term viability. If so, possible effects on *A. carolinensis*, which was observed microsympatrically and upon which *A. sagrei* is known to feed (Meshaka, *op. cit.*), will be of interest.

ASPIDOSCELIS LINEATTISSIMA (Many-lined Whiptail). MÉXICO: COLIMA: Isla Peña Blanca. 9 February 2007. Jaime Lúevano, Eric Mellink, and Mónica Riojas-López. Verified by Luis Canseco-Márquez. Colección Herpetológica, Museo de Zoología, Facultad de Ciencias, UNAM (MZFC 20090). First record for the island. The species is known elsewhere from lowlands of the adjacent mainland from Nayarit to Colima (García and Ceballos. 1994. Field Guide to the Reptiles and Amphibians of the Jalisco Coast, Mexico. Fundación Ecológica de Cuixmala, A.C. and Instituto de Biología, U.N.A.M, Mexico D.F. 184 pp.). The species is especially common amid rocky outcrops located on highest portion of the island.

RIOJAS-LÓPEZ**, Centro Universitario de Ciencias Biológicas y Agropecuarias, Universidad de Guadalajara, Km. 15.5 carretera a Nogales, 45100 Zapopan, Jalisco, México.

ASPIDOSCELIS TIGRIS MUNDA (California Whiptail). USA: CALIFORNIA: Plumas Co.: North Fork Feather River Canyon at Rock Creek, along north edge of unnamed dirt road 0.9 mi. NE of intersection with Highway 70 (39.90480°N, 121.35609°W; datum: WGS84; 695 m [2280 ft.] elev.). An adult female (California Academy of Sciences 237055; 69.7 mm SVL; 136.2 mm TL; 8.3 g [preserved weight]) . 22 June 2007 at 1434 h. New county record (Koo and Vindum 1999. Amphibians and Reptiles of the Plumas National Forest: Historical Collections and California Academy of Sciences 1998 and 1999 Surveys. Unpubl. report on file, Department of Herpetology, California Academy of Sciences. San Francisco, California). In neighboring Butte County, *A. tigris munda* is found between 200–650 m (656–2133 ft.) elevation in chaparral and mixed chaparral-foothill woodlands (Hayes and Cliff 1982. Herpetol. Rev. 13:85–87), and has been documented in the North Fork Feather River Canyon along the right bank just upstream of the confluence with Bear Ranch Creek (39.8439°N, 121.3968°W; pers. obs.), near the intersection of Cedar Creek and the railroad tracks (39.8434°N, 121.4063°W; pers. obs.), and adjacent to an unnamed tributary along the railroad tracks (39.8431°N, 121.4096°W; CAS 235786).

VINDUM,** Department of Herpetology, California Academy of Sciences, 875 Howard Street, San Francisco, California 94103, USA.

ASPIDOSCELIS SEXLINEATUS (Six-lined Racerunner). USA: MISSOURI: St. Francois Co.: Pond adjacent to Indian Creek Road, northeast of Iron Mountain Lake (37°42'50.5"N, 90°35'48.3"W). A clear photo was taken prior to a failed attempt to capture the lizard. 11 July 2007. Tony Gamble and Eli Greenbaum. Verified by Greg Watkins-Colwell. YPM Herp Media collection No. 1188. Fills a distributional gap in southeastern Missouri (Johnson 2000. The Amphibians and Reptiles of Missouri, Second ed. Missouri Dept. of Conservation. Jefferson City. 200 pp.). First county record with specific locality data (Daniel and Edmond. 6 February 2006. Atlas of Missouri Amphibians and Reptiles for 2005. http://atlas.moherp.org/, Accessed 25 July 2007).

CHAMAELEO AFRICANUS (African Chamaeleon). MAURITANIA: TRARZA REGION: Boû Tâfrâouat (17°05'N, 16°04'W). 30 August 2006. Mohamed Ould Salem. Institut de Recherche pour le Développement at Dakar (IRD TR 2166–2167). Verified by Youssouph Mané. Second record for Mauritania. Two specimens found in acacia trees. Extends range ca. 100 km N from Diawling National Park where it was cited without reference to specific locality or voucher information (Nickel 2003. Ökologische Untersuchungen zur Wirbeltierfauna im südöstlichen Mauretanien. GTZ, Echborn, 89 pp.; Padial 2006. Graellsia 62:159–178). Before these records, the westernmost locality in Africa for this species was 18 km NNE Didieni in Mali (14°05'N, 08°02'W), i.e., ca. 920 km E of Mauritania (Joger and Lambert 1996. *In* Ulrich [ed.], Tropical Biodiversity and Systematics. Proceeding of the International Symposium on Biodiversity and Systematics in Tropical Ecosystems, Bonn, 1994. Zoologisches Forschunginstitut und Museum Alexander Koening, Bonn, pp. 189–202). These records provide evidence for the continuous distribution of *C. africanus* south of the Sahara in the Sahel savannah from Sudan to the At-

lantic Ocean.

COLEODACTYLUS AMAZONICUS. BOLIVIA: DEPARTMENT PANDO: Federico Román Province: Río Negro (09°50'S, 65°39,W; 115 m elev.). 8 November 2002. L. Gonzales. Museo de Historia Natural Noel Kempff Mercado, Santa Cruz, Bolivia (MNKR 4316). Puerto Abuná (09°47'15.8"S, 65°32'00.5"W; 98 m elev.). 2 November 2006. A. Muñoz. Museo de Historia Natural Pedro Villalobos, Pando, Bolivia (MHNPV-R 405). Verified by J. Aparicio. Specimens found in the leaf litter in forest, active during the day. Previously known from eastern and central Amazonia in Brazil, French Guiana, Suriname, southern Guyana, and southern Venezuela (Avila-Pires 1995. Zoologische Verhandelingen 299:1–706). First country records extend known distribution 215 km E from Seringal Catuaba, 23 km E of Rio Branco in Brazil, the nearest record known (Avila-Pires, *op. cit.*).
